 UserId="31846" Text="You've brought up some very good points. Let's walk through all of this:

A word embedding is a mathematical representation of a word. 
This is needed since we cant work with text as plain input.

In order to get these word embeddings, there a different ways, methods and settings on how to calculate them. cbow, skip-gram and so on.


There are different pretrained word embeddings out there e.g.

 - [Fasttext][1] 2017, trained on Wikipedia; [cudos to Bojanowski, Piotr and Grave, Edouard and Joulin, Armand and Mikolov, Tomas][2] 
 - [Word2Vec][3] 2013, trained Google News dataset; [cudos to Tomas Mikolov, Kai Chen, Greg Corrado, Jeffrey Dean][4]
 - [Glove][5] 2013, Wikipedia 2014 + Gigaword 5; [cudos to Jeffrey Pennington, Richard Socher, Christopher D.

Manning] [6] This is just an excerpt of the most well-known ones. As you can see, they used different data sets - thus different word vocabulary and word embeddings respectively. I don't understand what is the real difference between these approaches regarding the desired outcome? Maybe the internal-only solution is not a semantic representation? What is the point of applying embedding layer to an external matrix of which the rows already have fix length? Keras is an awesome toolbox and the embedding layer is a very good possibility to get things up and running pretty fast. Convert the text into one-hot/count matrix, use it as the input into the word embedding layer and you are set. On the other hand if you use pre-trained word vectors then you convert each word into a vector and use that as the input for your neural network. This approach would give you more flexibility when it comes to feature engineering. As mentioned above, pre-trained word vectors were given mostly general text data sets. You might run into the point where you have some special kind of data (e.g. Tweets) where people write or behave differently. So you might look into training your own embeddings, on your own dataset - at the end of the day it depends on your task/problem and the metrics that you are tuning towards. Moreover, what is the purpose/effect of the trainable parameter of the Embedding layer? As you said correctly, it is to retrain the weights of the embeddings with the data set you use. I cannot understand what is the point to explicitly sign the end of sentence in a sentence based input. One of the most important things in NLP is feature engineering. It is the same as you sitting in school and learning a language, what needs to be considered, vocabulary, it's grammar and rules. Things that makes it easier for you as a human being to understand the language. The same is applied here. You can see it as one part of feature engineering, it all sums up to the bigger picture. And finally: how could a model predict the translation of a word which is not represented in the training set? Either you convert the word that couldn't be found to an `<UNK>` token (unknown word) which then represents its group. However it requires having the `<UNK>` token in the trained word embeddings. Or you could use fasttext binary file, which calculates word vectors on the fly for unknown words. [1]:

 UserId="29575" Text="> Why would we want a custom tokenizer?
 

Segmentation is a very large topic, and as thus there is no
 perfect Natural Language Tokenizer. Any toolkit needs to be flexible, and the
 ability to change the tokenizer, both so that someone can experiment, and so
 that it can be replaced if requirements are different, or better ways are found

for specific problems, is useful and important.
How could I measure if it was better that NLTK's tokenizer?
Anytime you are trying to quantify *performance* (ie: better) you will need to first define what is meant by better. Once this is done, then typically you would perform the using the various methods under measurement, and then compare the results against your definition of better. A couple of links which discuss these topics:
- [Performance of Different NLP Toolkits in Formal and Social Text] [2]
- [Optimizing to Arbitrary NLP Metrics using Ensemble Selection] [3]

genres.

According to your comment, you don't have any training data, just a list of keywords associated with each genre.

You can try computing the similarity between each document and each keyword list:

 1. [Normalize](https://en.wikipedia.org/wiki/Text_normalization) the document (convert to lowercase, remove punctuation, diacritics, non-alphanums, etc)
 2. Remove [stopwords](https://en.wikipedia.org/wiki/Stop_words)
 3. Convert the document to [tf-idf](https://en.wikipedia.org/wiki/Tf%E2%80%93idf) vector over your genre keyword vocabulary: Each document gets an n-length vector where each entry is the frequency of the ith genre keyword in the document. Normalize this vector to magnitude 1.
 4. Convert each genre keyword list to a tf-idf vector in the same way (again over the keyword vocabulary for all genres).
 5. Compute the [cosine similarity](https://en.wikipedia.org/wiki/Cosine_similarity) between the document vector and each genre vector.

For each document, this will give us a number in the range [0,1] for each genre. For example:
 
 Comedy Drama Fiction Romance Mythology Adventure

 UserId="43921" Text="I have several thousand text documents and I am currently working on obtaining the latent feature representations of words and generate

sentences using variational auto encoder. The main obstacle I am facing is "how to input such large textual vectors into VAE (or say even in a simple auto encoder)". I know there are other techniques such as adding layers in the form of LSTMs, but I want to keep it simple and keep the model as just VAE. One way is to use one-hot-encoded vectors or bag of words, but again, this is not the most efficient way since for a vocabulary of 100K unique words, each document will have a 100K input vector. Additionally, we loose the sentence structure. For small datasets however, there is no problem in training an autoencoder using this type of input. Another method is to use word embeddings using a pre-trained Word2Vec. This is what I have been trying to do and the python notebook which can be [DOWNLOADED HERE] [1] uses this technique. The code is too long and has multiple pre-processing steps, so I am unable to embed this code in my post. The following are my questions:

- Now, each sentence (or document) will have different number of words. So the number of word embeddings for each document will have different lengths. Unfortunately, keras requires all the inputs to be of same length (if I am right). So, how to handle such cases of varying input lengths?. Currently, in the fifth block of the python notebook, you can see the statement ``data = [x for x in vect if len(x) == 10]``. That is, I only consider documents that have exactly 10 words to overcome this problem. Ofcourse, this is not practical. Can we pad 0 vectors?
- The VAE example shown in [Keras blog] [2] uses MNIST data as exmple. Therefore, they use a `*sigmoid activation*` in the final reconstruction layer; consequently, `"*binary_crossentropy"` as the loss function (along with the KL divergence). Since my inputs are word embeddings, where there are even negative values in the embeded vectors, I believe I should not use the activation as `"*sigmoid"` in the final reconstruction layer. Is that right?. Additionally, I have also changed the loss as `"*mean_squared_error"` instead of `"*binary_crossentropy"` in the attached code. It will be great if someone who has worked on VAE and autoencoders for text data can provide their inputs regarding the questions mentioned above.

Note: the attached code is a simplified version of the code in [THIS LINK] [3]

 UserId="30578" Text="This question will invite a lot of opinions and it will be very specific to the problem that you are looking at. But there's no harm in laying out the popular options - $\frac{1}{2} \frac{1}{2} \frac{1}{2}$. Start with the data $\frac{1}{2} \frac{1}{2} \frac{1}{2}$. Images $\frac{1}{2} \frac{1}{2} \frac{1}{2}$; - If you are working with images and plan to use a classifier like `ConvNet`, PCA probably isn't a very good idea. You should just resize the image using popular libs like `opencv` $\frac{1}{2} \frac{1}{2} \frac{1}{2}$. Unstructured --> Word Count (195)

I am using the code from,
https://github.com/emara-geek/object-recognition-tensorflow/blob/master/src/main/java/com/emaraic/ObjectRecognition/Recognizer.java

(another example)
https://github.com/tensorflow/tensorflow/blob/master/tensorflow/java/src/main/java/org/tensorflow/examples/LabelImage.java

It works for Inceptionv3 models, and for models retrained from Inceptionv3.

But for MobileNet models it does not work, (such as following this article) https://codelabs.developers.google.com/codelabs/tensorflow-for-poets/

The code works, but gives the wrong results (wrong classify labels). What code/settings are required to use MobileNet from Java?

The code that works for Inceptionv3 is

 try (Tensor image = Tensor.create(imageBytes)) {
 float[] labelProbabilities = executeInceptionGraph(graphDef, image);
 int bestLabelIdx = maxIndex(labelProbabilities);
 result.setText(""");
 result.set --> Word Count (646)

 UserId="8878" Text="Nice question!

Some Remarks
 ##
For imbalanced data you have different approaches. Most well-
 stablished one is [resampling][1] (Oversampling small classes /underssampling
 large classes). The other one is to make your classification hierarchical i.e.
 classify large classes against all others and then classify small classes in
 second step (classifiers are not supposed to be the same. Try model selection
 strategies to find the best).

Practical Answer
 ##

I have got acceptable results without resampling the data!
 So try it but later improve it using resampling methods (statistically they are
 kind of A MUST).

TFIDF is good for such problem. Classifiers
 should be selected through model selection but my experience shows that Logistic
 Regression and Random Forest work well on this specific problem (however it's
 just a practical experience).

You may follow the code bellow
 as it worked simply well then you may try modifying it to improve your
 results:


 train = pd.read_csv(...)

 test = pd.read_csv(...)

 UserId="8878" Text="## Problem 1: "Tactic Titles" Are Really TEXT
 ##
i.e. they are not standard "tags". I say this because they
 seem so structured and tag-like. For instance in text analysis using NLP
 techniques you mostly deal with texts in which "Review Comments" and
 "Reviewing Comments" and "Comment Review" are supposed to be
 considered the same. 

Actually the way you already tried is a
 valid way to do it.

Another idea could be using information
 theoretic approaches. It means using something like Tf-IDF approach but this

time taking classes into account. Here you are going to look for words/n-grams which appear a lot in desired class (**High**) and not a lot in the other class. A simple formulation could be:

$$\text{Score}_{w_i} = \frac{N_{\text{high}}}{N_{\text{low}} + 1}$$

where N_{high} is the number of times the word w_i appeared in class **High** and N_{low} is the number of times the word w_i appeared in class **Low**. The constant 1 is just a smoother to avoid a zero denominator.

If you use it be careful about overfitting as you are learning features in a very implicit and hand-crafted way. To avoid overfitting you may prune your found words based on a *min_count* or *max_count* limitation.

Of course this is a simple score and you can improve it by modification (e.g. i did not consider the normalization which is better to be considered, etc.)

For prediction you can also simply use naive Bayes. Count words/phrases based on Bayesian approach (just count the frequency of words happening in each class) and normalize them to probabilities. Now you have most likely data given classes and the probability of classes. A new data comes and $P(C|D) = P(D|C) \times P(C)$ is calculated easily.

Problem 2: The "Tactic Titles" Are Just Fixed Tags (Maybe irrelevant to score)

Means that semantics are not correlated with classes i.e. two titles with similar terms or meanings might be in two different classes.

Then it's not a learning problem. Either you have the label of the new data in the dictionary so you just extract the class, or you don't have it so you don't know about it!

How would you want to know that "Partner Launch" is low priority but "Review Comments" is high if you have no meta-information from the organization behind it? How can you predict that based on this most probably "Write Comments" is **High** or **Low**? .If you argue that Machine Learning is supposed to learn that latent variable behind, then I would say yes! but please note that maybe that latent phenomenon is not correlated with ** -->

 UserId="1330" Text="A working example of a Variational Autoencoder for Text Generation in Keras can be found [here][1].

Cross-entropy loss, aka log loss, measures the performance of a model whose output is a probability value between 0 and 1 for classification. Cross-entropy loss goes up as the predicted probability diverges from the actual label. In the case of character-by-character autoencoder, each character in the vocabulary would be a label.

Cross-entropy works if the input and output are the same size, that is the case in character-by-character autoencoder. Often times in text analysis, the input and output sequences are different lengths so a second term, [encoder loss][2], is added to the objective function.

 UserId="13232" Text="The FastText binary format (which is what it looks like
 you're trying to load) isn't compatible with Gensim's `word2vec` format; the
 former contains additional information about subword units, which `word2vec`
 doesn't make use of.

There's some discussion of the issue
 (and a workaround), on the FastText Github page. In short, you'll have to load
 the text format (available at
[https://github.com/facebookresearch/fastText/blob/master/pretrained-](https://github.com/facebookresearch/fastText/blob/master/pretrained-vectors.md)
[vectors.md](https://github.com/facebookresearch/fastText/blob/master/pretrained-vectors.md)).

Once you've loaded the text format, you can use
 Gensim to save it in binary format, which will dramatically reduce the model
 size, and speed up future
 loading.

 UserId="46505" Text="Assuming you already have the raw text, you can do the followings.

 **Create train data:

 You need to create set words and bigrams labeled as skills. There might be some available lists to help you out. Otherwise, generate your list using resources such as wordnet and thesaurus. You can also start with a short list based on the

data you have and then expand it using word2vec or similar word embedding techniques. For example, we start with a list that contains **coding** as one of the skills. Then, we query the word2vec pretrained model for closest words/bigrams. There is a fair chance you will end up with **programming**, **software coding**, and **computer programming**. Another approach would be to cluster the words and bigrams in your dataset using word embedding techniques. Then, look into your clusters to see which ones contain the skill set. Note that any word/expression not on your list will not be considered as required skills. Therefore, you may need to expand your list after a few trials. ***Detecting the Skills*** 1. Tokenize your raw text into words and expressions 2. Remove stop words 3. Encode your tokens using an embedding (Word2Vec, Fast --> Word Count (51))

Methods include machine-learning and rule-based approaches. It is often regarded as the engineering arm of Computational Linguistics.

 NLP tasks

 * Text pre-processing
 * Coreference resolution
 * Dependency parsing
 * Document summarization
 * Named entity recognition (NER) [tag:named-entity-recognition]
 * Information extraction (IE) [tag:information-retrieval]
 * Language modeling
 * Part-of-speech (POS) tagging
 * Morphological analysis and wordform generation
 *

Phrase-structure (constituency) parsing 
 * Machine translation (MT)
 [tag:machine-translation]
 * Question answering (QA)
 *
 Sentiment analysis [tag:sentiment-analysis]
 * Semantic parsing
 
 * Text categorization

 UserId="32220" Text="I am working on text analysis problem.

 
Person X can log in his goals and his actions to achieve his goal.
 Also their score is calculated based on some formula to measure progress of the
 goal

*For ex:**

 - Goal1 : Loose weight
 ... Score: 70%
 - Goal2: Finish reading this book... Score:
 10%
 - Action1: Go to the gym
 - Action2: Drink
 water
 - Action3: Read one page
 daily



Goals and actions don't have any
 relationship in my db, so i joined them based on the person

I
 have as an input

 +-----+-----+-----+-----+

 | Goal | Action | Person | Score |

 +-----+-----+-----+-----+

 | Lose weight | Go to the gym | X | 70 |

 | Lose weight | Drink water | X | 70 |

 | Lose weight | Read one page daily | X | 70 |

 | Finish reading this book | Go to the gym | X | 10 |

 | Finish reading this book | Drink water | X | 10 |

 | Finish reading this book | Read one page daily | X | 10 |

 +-----+-----+-----+-----+

 D;
I want to detect what are the good actions that can have high score and
 what are the bad actions that can have low score

My
 Approach:

 1. Apply clustering

algorithm on Goals to find similar groups of goals then study their actions
 2. My --> Word Count (720)

 UserId="381" Text="I haven't seen anything like this before but it seems quite feasible. You need an ontology to separate the main concept into its subconcepts, then you need a classifier to distinguish between your broader categories; description, methodology, classifier, application, and example. That is, I would manually label some transcripts at the paragraph level. If you don't have paragraph-segmented text, smooth the classification probability over the sentences so they share the same label. The classifier could be a CRF or an RNN. The modern way to induce the ontology would be through word embeddings; cf. e.g, [Learning Semantic Hierarchies via Word Embeddings](<http://ir.hit.edu.cn/~car/papers/acl14embedding.pdf>). Formerly I would have recommended a hierarchical topic model, such as hLDA; cf. e.g, [Non-Parametric Estimation of Topic Hierarchies from --> Word Count (21)

 UserId="39423" Text="You are probably trying to load word vectors that are shared in the fasttext.cc website or are trying to load using models that are trained with the latest one on master. There is [an issue in github](https://github.com/salestock/fastText.py/issues/115) with a lot of comments. One solution is to try to load from the text files the code for which is given [here][1]. I was able to work around this using java but had to train it in java only. Take a look at the examples in this package.

 UserId="13023" Text="1.- Ideal true vs false ratios don't exist and they should reflect the the reality the best they can, you can always remove negatives if the ratio is too skewed to improve training speed though. Let me explain it with

an example. Ads CTR is as old as the internet and it's skewed to less than 1% positives vs. plus 99% negatives. Yet, data scientists prefer to train it on the entire dataset because many negatives will include information that models couldn't find otherwise. They might not provide a lot of information as a positive one but they are still somewhat important. There are approaches where CTR ratios get artificially rebalanced by sampling in case you want a swifter training and it will still work. In your case, positives are 0.4% which resemble CTR on ads so you can: gather more data to increase the number of positives in order to better understand what makes an article interesting. In case that is not possible trying ensembles which often improve prediction

performance.

2.- Clustering is an unsupervised approach so you would be losing information by doing so (training labels) besides, sentence embeddings (representations) of one big cluster of negatives and a tiny cluster of positives do not convey information as well as word embeddings which have already been trained on billions of documents.

A better approach is:

1) to use multiple models and compare their performance on this dataset. I have the impression that there will be certain keywords that make articles interesting, so a bag of words will still be helpful, even as a starter model. 

2)Use feature engineering. Your model might be overlooking important features, such as article length, reading time, number of paragraphs, ratio of complex words (measured by length), etc. Feature engineering is always important in case you haven't used it yet.

3)Use pretrained embeddings. CNN and RNN models can use pretrained embeddings such as GloVe, Word2Vec or Fast --> Word Count (36)

 Text="1.- Ideal true vs false ratios don't exist and they should reflect the the reality the best they can, you can always remove negatives if the ratio is too skewed to improve training speed though. Let me explain it with an example. Ads CTR is as old as the internet and it's skewed to less than 1% positives vs. plus 99% negatives. Yet, data scientists prefer to train it on the entire dataset because many negatives will include information that models couldn't find otherwise. They might not provide a lot of information as a positive one but they are still somewhat important. There are approaches where CTR ratios get artificially rebalanced by sampling in case you want a swifter training and it will still work. In your case, positives are 0.4% which resemble CTR on ads so you can: gather more data to increase the number of positives in order to better understand what makes an article interesting. In case that is not possible trying ensembles which often improve prediction performance.

2.- Clustering is an unsupervised approach so you would be losing information by doing so (training labels) besides, sentence embeddings (representations) of one big cluster of negatives and a tiny cluster of positives do not convey information as well as word embeddings which have already been trained on billions of documents.

In addition, running k-means on categorical variables will yield anomalous clusters because it's meant to be used with continuous variables. You can find more information about the topic on the following links:

<https://stats.stackexchange.com/questions/58910/kmeans-whether-to-standardise-can-you-use-categorical-variables-is-cluster-3>

<https://datascience.stackexchange.com/questions/22/k-means-clustering-for-mixed-numeric-and-categorical-data>

<https://www.kaggle.com/general/19741>

<https://www.quora.com/Why-does-K-means-clustering-perform-poorly-on-categorical-data-The-weakness-of-the-K-means-method-is-that-it-is-applicable-only-when-the-mean-is-defined-one-needs-to-specify-K-in-advance-and-it-is-unable-to-handle-noisy-data-and-outliers>

Therefore, you should use high dimensional embeddings or representations to cluster meanings together, this has been explored in word meanings but for sentences or articles, a vector representation becomes more complicated to implement. One possible approach is the Word Movers' Distance but there are many more possible approaches, you should google them. In addition a non-linear clustering algorithm such as t-sne

will probably yield better results than k-means using the embeddings approach.

A better approach is:

1) to use multiple models and compare their performance on this dataset. I have the impression that there will be certain keywords that make articles interesting, so a bag of words will still be helpful, even as a starter model.

2)Use feature engineering. Your model might be overlooking important features, such as article length, reading time, number of paragraphs, ratio of complex words (measured by length), etc. Feature engineering is always important in case you haven't used it yet.

3)Use pretrained embeddings. CNN and RNN models can use pretrained embeddings such as GloVe, Word2Vec or Fast --> Word Count (36)

 UserId="51321" Text="I am classifying text using [fastText][1] which is a word2vec library that can also create vectors for character level n-grams and I have successfully trained a binary classifier.

Now I'd like to see what words or subword n-grams are the most predictive of a class for the two classes (e.g. if classifier sees a word `forest` or a subword `res` then that might be a strong indication that the document has label `Nature`, but if it sees word "and" then that is probably not very informative for this classification task).

Therefore, I guess the question could be phrased as:

**Given vectors representing words and subwords and a trained fastText classifier, what would be the best way to get a list of e.g. top 10 most informative words and subwords for deciding which class

a sample belongs to?*

Even though I'd be glad if you could make specific suggestions that consider my current setup with fast --> Word Count (13)

–Text Classification– is a form of supervised learning, hence the set of possible classes are known/defined _in advance_, and won't change.

–Topic Modeling– is a form of unsupervised learning (akin to clustering), so the set of possible topics are unknown _apriori_. They're defined as part of generating the topic models. With a non-deterministic algorithm like LDA, you'll get different topics each time you run the algorithm.

 UserId="14006" Text="I have worked on lexicon level token normalization on twitter data, which seems to be very similar to what you are trying to do. In our task, we were not only normalizing *short word*, but also "welllll",>"well", "lysm",>"love you so much", "2",> to, etc. Refer to the task description [here] [1]. At that time we did not find a good library directly for this job. 

In our approach, we resort to buidling a lookup table to replace *suspicious* words. The lookup table is compiled from the following resources:

[Huge List of Texting and Online Chat Abbreviations] [2]

[Twitter Dictionary: A Guide to Understanding Twitter Lingo] [3]

[Lexical normalisation of

short text messages: makn sens a #twitter] [4]

 UserId="1330" Comment="added 164 characters in body" Text="It depends on the signal-to-noise in the dataset. The amount of data to perform named entity disambiguation will depend on the [tf-idf score][1] of the occupation and skills, rare occupations and skills will require less data to build a performant model.

For example, that the sentence "I am a cook that multitasks well." "Cook" is an occupation and "multitask" is a relevant skill. In a similar sentence, "I

multitasked while I cooked." "Cook" is no longer an occupation and "multitask" is no longer a relevant skill. However, the phrase "saturation diver" is less frequent than "cook", thus much easier to build a model to identify as an occupation and find relevant skills.

Annotator performance is easier to measure. [Cohen's kappa][2] is a common method of judging [inter-rater reliability][3]. Again, the number of needed raters depends on their agreement on the task. If task performance is easy, the number of raters and the number of items per rater can be lower. It is best to benchmark your system and then decide how much data you need to raise the benchmark scores.

One way to automatically create ontologies from a text is the [--> Word Count (16)

 UserId="44039" Text="> Their outcomes X are dependent because they must be summed to n 

If you are really want to model multiple experiments probabilistically, please do not forget the normalization constant that make the unnormalized quantity normalized by integrating/summing them to one. 

Multinomial Naive Bayes model, as described by Manning et al (2008), estimates the conditional probability of a particular word/term/token given a class as the relative frequency of term t in documents belonging to class c: 

[!enter image description here][1][1]

Thus this variation takes into account the number of occurrences of term t in training documents from class c, including multiple occurrences **Not multiple experiments.**

 UserId="29587" Text="A generative model is able to generate instances from a

given distribution. So let's try to get our model to generate instance from the distribution of all hand written digits. This includes numbers 0 to 9 and for each of these numbers there are a very large set of possible way of writing the same number. Take the number 4 from the MNIST dataset, which are comprised of handwritten numbers. 

[![enter image description here][1]][1]

You can quickly see how many different ways each of these numbers can be written yet still represent the same value. This is the distribution we want to capture using our generative model. The model works by training a generator to effectively try and cheat a discriminator that has been trained to distinguish between real and artificial instances from the desired distribution. When the discriminator can no longer distinguish between the artificial and real instances, we can say the generative model can successfully produce examples which match this distribution. 

In other words, once the generator starts producing realistic digits, we can say that the generator is producing instances which match the instances captured in the MNIST dataset. 

[![enter image description here][2]][2]

This idea of matching a distribution can be applied to wide range of applications where you want to draw from a distribution. Some for demonstration purposes of the techniques without any real useful application and some very useful applications which are currently being used for a number of tasks. Here is a short lists of some examples:

- [Generating artificial faces][3]

 UserId="45064" Text="There are two basic approaches to summarization:
 abstractive and **extractive**.

Extractive
 summarization is simpler and consists of selecting informative pieces/sentences
 from text. It is commonly performed using algorithms like TextRank (a variation
 of PageRank). An example implementation can be found in [gensim][1]. There are
 other approaches, for example check out [sumy][2]
 library.

Abstractive summarization on the other hand
 consists of summarizing documents with shorter sentences which do not have to
 come from the input text (an abstract may paraphrase some fragments of text). It
 is commonly performed using Deep Learning Seq2Seq
 methods.

Which approach is better for start? **Extractive**
 wins by far. First of all, you don't have to train any model, as these methods
 rely on information found solely in summarized text. Second, deep learning
 models, even if they exist and can be easily found *, are trained on specific
 texts, so they might not generalize well across application
 domains.


> But How should be the approach , when the
 dataset also has documents

> in french, chinese, hindi

etc...

If you have good tokenizers and stemmers for these languages you should be fine with --> Word Count (72)

 UserId="54246" Text="Since you are specifically asking about deep learning techniques, nothing strikes me out of the bat other than [Autoencoders](https://en.wikipedia.org/wiki/Autoencoder).
 

You can try using autoencoders for clustering, basically, you need to stick with clustering. Since you don't have the labels.

To answer your question whether they rely on

embeddings that are out there, it depends on your data, if you have a domain-specific data or you have the data in a weird language then you should go for creating your own embeddings. I found this article really helpful, though it has been done on images, you can try it on text, using `Conv1D`. Also yes, you can try out word embeddings like [word2vec](https://en.wikipedia.org/wiki/Word2vec) or [fasttext](https://github.com/facebookresearch/fast

 UserId="45264" Text="With your three labels: positive, neutral or negative - it seems you are talking more about **sentiment analysis**. This answer the question: **what** are the emotions of the person who wrote this piece of text?
Semantic analysis is a larger term, meaning to analyse the meaning contained within text, not just the sentiment. It looks for relationships among the words, how they are combined and how often certain words appear together.
 To gain a deeper insight into your text, you could read about topics such as:
 Semantic Analysis in general might refer to your starting point, where you parse a sentence to understand and label the various parts of speech (POS). A tool for this in Python is **spaCy**[1], which works very nicely and also provides

visualisations to show to your boss.
* Named Entity Recognition (NER) - finding parts of speech (POS) that refer to an entity and linking them to pronouns appearing later in the text. An example is to distinguish between *Apple* the company, and *apple* the fruit.
* Embeddings - finding *latent* representation of individual words e.g. using **Word2Vec**. --> Word Count (245)

 UserId="56380" Text="**The main idea here is: "birds of a feather flock together"** That is, words that appear near each other inform the "function" of a word.

More importantly, I think of the techniques you mentioned as "methods," rather than "models." The reason why is it seems possible to violate the definition of what a [distributional semantic model](https://en.wikipedia.org/wiki/Distributional_semantics) is without appropriate data preprocessing.

SVD for example, is typically a dimensionality reduction technique, or the pre-cursor to a clustering technique depending on feature engineering and usage of the methodology. In this case, if you were counting the co-occurrence of words across documents -- rows = documents, cols = words, cells = # of times that word appeared in that particular document -- and then you ran SVD on that, you might have the pre-

cursor to a "model" that may eventually be something you can call distributional semantic.

Another example could be Word2Vec, where one typically uses a neural network to train a shallow layer, and extract the weights. Word2Vec can be trained via Skip-gram, or continuous bag of words. Since the "meaning" of a word is derived from the co-occurrence and/or proximity to neighboring words, it may be considered a distributional semantic model. Fast --> Word Count (53)

 UserId="58789" Text="POS can be used in multiple application in text analytics.
 The majority of the techniques in Text Analytics work on tokenisation and N
 grams(break down of sentence into words). In most of the case, semantics of the
 text is lost as sentences are break down into words and standalone words cannot
 express emotions and semantics as compare to group of words or sentences. So by
 tagging each word in the corpus to its parts of speech makes sometimes easy to
 get the context in which the word is used and ultimately used in analyzing the
 sentiments.

 UserId="60742" Text="There's all sorts of rules of thumb for the structure of a neural net (if n features use n+1 or 2n or 1.5n nodes, etc). I wouldn't take any of them as gospel.

The size and structure of your neural network chiefly depends on the complexity of the data you're trying to learn. If your data is already pretty well represented by, say, linear regression, then you don't really need much additional size to your neural network to represent it well. On the other hand, if your five inputs were, say, the move and shoot commands of a recording of a game of Doom, you're gonna need a large neural network to accommodate all the deep and meaningful interactions between the individual commands. 

Each successive layer of nodes of a neural network deals with increasingly complicated shapes. The first hidden layer is all sigmoid or ReLU functions, the second layer is combinations of the first layer, the third is combinations of the second layer, etc. 

The general structure of the hidden layers is cone-shaped, tapering towards the right. There are lots of nodes in the first layer, and fewer in each successive layer. You can have constant numbers of nodes per layer, though in my playing around it doesn't seem to help much, and many of the layer nodes go relatively unused. The opposite direction (having few first layer nodes and many last layer nodes) is actively harmful, because the later nodes can only ever be combinations of the earlier nodes, and if the first nodes don't create enough shapes for the later nodes to combine, it won't be able to fit anything. 

I've provided a couple of interactive examples through tensorflow's playground.

[Normal structure (Decreasing nodes per layer)] [1]

[Same no. of nodes per layer] [2]

[Rising no. of nodes per layer] [3]

The first two should converge relatively easily, whereas the third shouldn't converge at all.

 UserId="8878" Text="Have a look at [this][1] to see how a Knowledge Base can be built. I would say the best way is to build your own Knowledge Base based on your corpus if you have enough data.

The idea (simplified) for starting is to have patterns such as "*NAME is POSITION*" by seeing some of data. Through this you find many names and positions. Then you extract new patterns from them and scan whole data again. Do it until no new pattern shows up. Then you end up with lots of is-a relations which is what you need.

For extracting positions you may need sentence segmentation. Have a look at [slide 56][2] onward to get an overview.

PS: If you do not have enough data, you may crawl web and get texts and try to make your lexical databases. Target websites with more probability of having such a context.

Hope it helps. Good Luck!

 UserId="62134" Text="Consider the fictional word tahiliuk in the sentence "We
 found a small, fluffy tahiliuk running around our garden." While hearing a new
 word used in context, people are remarkably adept at inferring a basic notion of
 a its meaning. 

Question: How the tahiliuk's vector could
 be learned from the context? 

Assumption: 
a
 fixed input vocabulary, mapped to a set of word
 vectors.

Remarks:

 1. Tahiliuk is a
 completely new word. There is now such word within
 training
 data.
 2. Using approaches like "fast --> Word Count (89)

 UserId="32628" Text="I am looking to compile a sentiment corpus for news
 articles in multiple languages (~100k per lang) where each article is labeled
 positive, neutral, or negative. I have searched high and low but could not find
 anything like this available. I already have the news articles in each
 language.

My question to the community is how would you
 achieve this as accurately as possible?

I was first looking
 at [Mechanical Turk][1], where you can hire people to label each article
 manually for you. And this may be the best way forward *but
 expensive*
[![enter image description
 here][2]][2]


Next, I thought about all of those
 existing popular libraries (some of whom have already used Mechanical Turk) that
 do sentiment analysis ([AFINN][3], [Bing Liu][4], [MPQA][5], [VADER][6],
 [TextBlob][7], etc.)

1. Sentiment Idea

My

current idea is that I run each news article across a few of these libraries (for example AFINN, then TextBlob, then VADER) and for those articles who show positive, negative, neutral unanimously though all three libs are accepted into the corpus. Does that seem like a fairly strong and reasonable verification process?

2. Language Idea

The next issue pertains to language itself. The 3 lib pipeline above can be executed in English with no issue. However these libraries do not uniformly support many other languages (Spanish, German, Chinese, Arabic, French, Portuguese, etc.) I was thinking about doing what VADER suggests and taking the news stories in non-english languages and sending them through Google Translation API to get them into English and then send them through the existing 3 lib pipeline above. I do realize there will be a loss in semantics for many articles. However, my *hope* is that enough articles will translate well enough that some pass through the 3 lib pipeline.

I am aware that translating and sending news articles through this triple blind sentiment pipe may take a 100k corpus and yield 10k results. I am fine with that. The accuracy and then price is my concern. I can easily acquire more data.

As a non data scientist, I ask what your opinion of this is? What would you do that may be a more accurate way of achieving a sentiment corpus of news articles?

UserId="32628" Comment="added 35 characters in body; edited tags" Text="I am looking to compile a sentiment corpus for news articles in multiple languages (~100k per lang. for a machine learning experiment) where each article is labeled positive, neutral, or negative. I have searched high and low but could not find anything like this available. I already have the news articles in each language.

My question to the community is how would you

achieve this as accurately as possible?

I was first looking at [Mechanical Turk][1], where you can hire people to label each article manually for you. And this may be the best way forward *but expensive*.

[!
enter image description here][2]]

Next, I thought about all of those existing popular libraries (some of whom have already used Mechanical Turk) that do sentiment analysis ([AFINN][3], [Bing Liu][4], [MPQA][5], [VADER][6], [TextBlob][7], etc.)

1. Sentiment Idea

My current idea is that I run each news article across a few of these libraries (for example AFINN, then TextBlob, then VADER) and for those articles who show positive, negative, neutral unanimously though all three libs are accepted into the corpus. Does that seem like a fairly strong and reasonable verification process?

2. Language Idea

The next issue pertains to language itself. The 3 lib pipeline above can be executed in English with no issue. However these libraries do not uniformly support many other languages (Spanish, German, Chinese, Arabic, French, Portuguese, etc.) I was thinking about doing what VADER suggests and taking the news stories in non-english languages and sending them through Google Translation API to get them into English and then send them through the existing 3 lib pipeline above. I do realize there will be a loss in semantics for many articles. However, my *hope* is that enough articles will translate well enough that some pass through the 3 lib pipeline.

I am aware that translating and sending news articles through this triple blind sentiment pipe may take a 100k corpus and yield 10k results. I am fine with that. The accuracy and then price is my concern. I can easily acquire more data.

As a non data scientist, I ask what your opinion of this is? What would you do that may be a more accurate way of achieving a sentiment corpus of news articles?

UserId="32628" Comment="deleted 61 characters in body" Text="I am looking to compile a sentiment corpus for news articles in multiple languages (~100k per lang. for a machine learning experiment) where each article is labeled positive, neutral, or negative. I have searched high and low but could not find anything like this available. I already have the news articles in each language.

My question to the community is how would you achieve this as accurately as possible?

I was first looking at [Mechanical Turk][1], where you can hire people to label each article manually for you. And this may be the best way forward *but expensive*.
[![enter image description

here][2]]


Next, I thought about all of those existing popular libraries (some of whom have already used Mechanical Turk) that do sentiment analysis ([AFINN][3], [Bing Liu][4], [MPQA][5], [VADER][6], [TextBlob][7], etc.)

1. Sentiment Idea

My current idea is that I run each news article across a few of these libraries (for example AFINN, then TextBlob, then VADER) and for those articles who show positive, negative, neutral unanimously though all three libs are accepted into the corpus. Does that seem like a fairly strong and reasonable verification process?

2. Language Idea

The next issue pertains to language itself. The 3 lib pipeline above can be executed in English with no issue. However these libraries do not uniformly support many other languages (Spanish, German, Chinese, Arabic, French, Portuguese, etc.) I was thinking about doing what VADER suggests and taking the news stories in non-english languages and sending them through Google Translation API to get them into English and then send them through the existing 3 lib pipeline above. I do realize there will be a loss in semantics for many articles. However, my *hope* is that enough articles will translate well enough that some pass through the 3 lib pipeline. 

I am aware that translating and sending news articles through this triple blind sentiment pipe may take a 100k corpus and yield 10k results. I am fine with that. The accuracy and then price is my concern. I can easily acquire more data. 

What would you do that may be a more accurate way of achieving a sentiment corpus of news articles? Is there an existing best used practice for assembling a corpus like this?

UserId="50406" Text="Cleaning data largely varies from data to data. Considering you are talking mostly about **unstructured data**, it can be of two types, namely ***Image data*** and ***text data***. The process of cleaning both these data depends on the type of goal required to be achieve using these. A little brief process could be explained as follows:

- ***Image data***: While performing convolutional neural network on the data, the process of feature extraction from the data is automated. Specific pre-processing need to be carried out aiming it to the target. This includes:
 - Keeping the data set close to the actual data on which the model is to be tested.
 - Removing any unnecessary images that do not co-ordinate with the corresponding label.
 - Resizing the images as per the model requirement.

- ***Text data***: --> Word Count (90)

 UserId="13023" Comment="added information requested in the comment." Text="PoS tagging works for natural language only and identifies grammatical parts of the sentence, nothing more. LSTM is an algorithm that can be used to predict series. [Named Entity Recognition (NER)][1] and [Terminology Extraction][2] could work if you have already data to engage in [Information Extraction (IE)][2]. However, In order to use a these techniques you need to have a trained model and in order to train one you need data. In your case that would involve identifying and tagging parts of the sentence by hand and later training a model with that data.
 

The best approach, in my opinion, is just use regex to identify parts of the sentence as one of the [approaches of Information Extraction][3] and use hard coded rules to best identify what you are trying to replace later.


For instance, if you want to search the version in the example:

> import re

> s = 'Releasing version. 0.0.1 for Stackoverflow, on 01/01/2019. The coverage is 99% and build is passed.'

> re.search(r'Releasing version.(.*?)for', s).group(1)

> ' 0.0.1 '

Check out these resources that will help you parse a log in Python using Regex.


[https://pythonicways.wordpress.com/2016/12/20/log-file-parsing-in-python/] [4]

[https://medium.com/devops-challenge/apache-log-

parser-using-python-8080fbc41dda] [5]

But if you prefer to use Named Entity Recognition or Terminology Extraction techniques you could hack a NER model and train it yourself with your data. Keep in mind though, that according to [Poibeau, Thierry; Kosseim, Leila (2001). "Proper Name Extraction from Non-Journalistic --> Word Count (126)

 from gensim.models.keyedvectors import KeyedVectors

 word_vectors = KeyedVectors.load_word2vec_format('wiki.simple.bin', binary=True)

But, it shows the following errors

 Traceback (most recent call last):
 File "nltk_check.py", line 28, in <module>
 word_vectors = KeyedVectors.load_word2vec_format('wiki.simple.bin', binary=True)
 File "P:\major_project\venv\lib\sitepackages\gensim\models\keyedvectors.py", line 206, in load_word2vec_format
 header = utils.to_unicode(fin.readline(), encoding=encoding)
 File "P:\major_project\venv\lib\site-packages\gensim\utils.py", line 235, in any2unicode
 return unicode(text, encoding, errors=errors)
 UnicodeDecodeError: 'utf-8' codec can't decode byte 0xba in position 0: invalid start byte


 Question 1 How do I load fasttext model with Gensim? 

 Question 2 Also, after loading the model, I want to find the similarity between two words 
 ``python
 model.find_similarity('teacher', 'teaches')
 # Something like this
 Output : 0.99
 ``
How do I do this?

 UserId="65719" Text="I am working on a multiclass classification which is to
 assign medical related queries of web search to certain departments of
 hospital.My classifier is based on the [fastText][1].
 <p>

I found for most conditions, the result is good
 enough say recall is 0.8 for Nephrology. However, for just one department,
 Dermatology, the recall is pretty low,like 0.5. Unfortunately, this label has
 most samples in the test data.<p>

How can I improve the
 recall of one class while maintain the performance of other classes? Will
 ensembling method work?

 UserId="2932" Text="A shell for the type of network architecture you might be looking for could reasonably be:

 {Input} -> {representation layers} -> {output}

Your question has a few implicit layers, first:

* How do I take input of various types (numeric data vs text data)
* How do I handle representations of the text data?
* How do I handle output for 380,000 output classes?

So, let's tackle these one at a time.

How do I take input of various types (numeric data vs text data)

The specific details of this are going to depend heavily on which framework you're using, as implementing this in base PyTorch is different than in Keras or Tensorflow, for example.

In any

```

case, you're likely going to want to define different inputs for the data types
you want to handle differently:&#xD;&#xA;&#xD;&#xA;    {Numeric Input}&#xA;|--
{Numeric Representation} -|&#xD;&#xA;
|&#xA;{Dense Layer(s)} --&#xA; {Outputs}&#xD;&#xA;    {Text Input} ---&#xA;|--
{Text Representation} ----|&#xD;&#xA;&#xD;&#xA;*&#xA;How do I handle representations
of the text data?*&#xD;&#xA;&#xD;&#xA;It sounds like you have an opinion for
this, and that you're wanting to try:&#xD;&#xA;&#xD;&#xA;    {Numeric
Input}&#xA;|-- {Numeric Representation} -&#xA;|&#xD;&#xA;
|&#xA;{DenseLayer(s)} -&#xA; {Outputs}&#xD;&#xA;    { --> Word Count (269)

UserId="47359" --> Word Count (1)
UserId="47359" Comment="added 4 characters in body" Text="There is a scientific
document that implements a convolutional neural network to classify **3
different types of data**, although how exactly, is unknown to
me.&#xD;&#xA;&#xD;&#xA;Here's the explanation of network
architecture:&#xD;&#xA;&#xD;&#xA;&#xA;> This section describes architecture of our
neural net which is&#xD;&#xA;&#xA;> depicted in **Fig. 3.**&#xD;&#xA;&#xA;> **Our
network has three types of inputs**: **Screenshot** (we use upper crop of the
page with dimensions 1280 × 1280, however this net can&#xD;&#xA;&#xA;> work with
arbitrarily sized pages), **TextMaps** (tensor with dimensions&#xD;&#xA;&#xA;>
$128 \times 160 \times 160$) and Candidate boxes (list of box coordinates
of&#xD;&#xA;&#xA;> arbitrary length).&#xD;&#xA;&#xA;> &#xD;&#xA;&#xA;> **A screenshot
is processed by three convolutional layers** (the first two layers are
initialized with pretrained weights from BVLC&#xD;&#xA;&#xA;> AlexNet). **TextMaps
are processed with one convolutional layer** with&#xD;&#xA;&#xA;> kernel size $1
\times 1$ and thus its features capture various&#xD;&#xA;&#xA;> combinations of
words. These two layers are then concatenated and&#xD;&#xA;&#xA;> processed by
final convolutional layer.&#xD;&#xA;&#xA;> &#xD;&#xA;&#xA;> [![[enter image
description
here][1]][1]&#xD;&#xA;&#xD;&#xA;&#xD;&#xA;---&#xD;&#xA;&#xD;&#xA;What exactly is
implied by **Our network has three types of inputs** above? Is it possible for
convolutional neural network to pass different types of inputs differently?
&#xD;&#xA;&#xD;&#xA;From my understanding, neural network for **Screenshot**
input would be created like this:&#xD;&#xA;&#xD;&#xA;      def CNN(features,
labels, mode):&#xD;&#xA;      input_layer = tf.reshape(image, [-1, 1280, 1280,
1])&#xD;&#xA;      &#xD;&#xA;      # Conv+ReLU&#xD;&#xA;      conv_relu_1 =
tf.layers.conv2d(&#xD;&#xA;      inputs=input_layer,&#xD;&#xA;
filters=96,&#xD;&#xA;      kernel_size=[11, 11],&#xD;&#xA;
padding=&quot;same&quot;,&#xD;&#xA;      activation=tf.nn.relu)&#xD;&#xA;
&#xD;&#xA;      # MaxPool&#xD;&#xA;      pool1 =
tf.layers.max_pooling2d(inputs=conv1, pool_size=[3, 3], strides=2)&#xD;&#xA;
&#xD;&#xA;      # Conv + ReLU&#xD;&#xA;      ...&#xD;&#xA;      &#xD;&#xA;So let's
say this is first neural network, then should I create another neural network

 your message Ahmed. There are things to point out:&#xD;&#xA;&#xD;&#xA; 1. \*Is  
 this an imbalanced problem?\* Which problem? \*\*THIS\*\* is not a problem. This is  
 data.&#xD;&#xA; 2. What analysis is going to be done? In some cases you need  
 posts and in some you need these keywords. &#xD;&#xA; 3. What method is going to  
 be done for that analysis? Some methods get keywords as input and some get  
 posts.&#xD;&#xA;&#xD;&#xA;&#xD;&#xA;But about the numbers themselves; Not  
 necessarily. The smallest class has 20% of the largest population and moreover,  
 the scale is pretty high (20000 samples). So it is not necessarily an imbalanced  
 class distribution. Again, see what you want to do with this data. That  
 determines the answer much more accurate.&#xD;&#xA;&#xD;&#xA;Hope it helped. If  
 you write about the task you want to do I can post the solution  
 here.&#xD;&#xA;&#xD;&#xA;Cheers,&#xD;&#xA;&#xD;&#xA;## UPDATE  
 ##&#xD;&#xA;&#xD;&#xA;Well, then the problem is pretty straight-forward. These  
 unique words are probably not much meaningful here. I certainly recommend that  
 you try BoW models first ([TF-IDF][1] and [classic BoW][2]) for modeling your  
 corpus. Then tune the hyperparameters of models and using a simple Multinomial  
 Naive Bayes you will get an acceptable result. &#xD;&#xA;&#xD;&#xA;Data is not

counted that imbalanced. I had a problem in which some classes had 3000-4000 samples and some only 20! That is certainly called imbalanced but here you still have enough data to represent your minority class and also you will use Precision-Recall for evaluation instead of Accuracy so you will be fine. I strongly recommend you to have a look at [this][3] for Python implementation and also seeing some imbalanced data in practice. The DL thing is answered in the comment.  For example, generation of text. &#xD;&#xA;&#xD;&#xA;In such problems, RNN is  
 designed to generate next character (It keeps track of what characters have  
 generated in past). RNN should generate "End Of Output" character to  
 indicate end of sequence. &#xD;&#xA;&#xD;&#xA;For example :

 UserId="61843" Text="Recently I started reading more about NLP and following tutorials in Python in order to learn more about the subject. I started experimenting with words embeddings also, and I found some interesting results which I don't know how to interpret. I first used an English corpus for both training and testing and afterwards, I used the English corpus for training and a small French corpus for testing (all corpora have been annotated for the same binary classification task). In both cases, I used the pre-trained on tweets Glove embeddings. As the results in the case where I also used the French corpus improved (by almost 5%, reaching ~accuracy = 0.8), I was wondering if Glove was

trained on multilingual data, as I didn't see anyone making this statement (I'm aware of the amount of data that is used) comparing to FastText, for example, where you have embeddings for different languages. Also, if Glove supports multilingual information, this would also eliminate the need for mapping different embeddings into the same embedding space (as is the case for Fast --> Word Count (8))

UserId="201" Text="What you need to look for is called "Named Entity
recognition". From [Wikipedia][1]

> Named-entity
recognition (NER) (also known as entity identification,
> entity
chunking and entity extraction) is a subtask of information
>
extraction that seeks to locate and classify named entity mentions
in
> unstructured text into pre-defined categories such as the
person
> names, organizations, locations, medical codes, time
expressions,
> quantities, monetary values, percentages,
etc.

As it is mentioned in the comments section, Stanford has
a great NER Tagger and you could use that together with Python (even if the
StanfordNLP is implemented in Java)

Download the jar file
from the [official url][1]. It has this format `stanford-ner-xxxx-xx-
xx.zip`

You need to put the following two files in the same
application folder as your Python script

1. ner-
tagger.jar
2. ner-model-english.ser.gz (choose another one if you don't
want
English)

import nltk

 from nltk.tag.stanford import
StanfordNERTagger 

 yourText =
this_is_your_text

If your dataset is made of plain text or other type of factors (i.e not numbers) then it wont work for you . You need to do another step of preprocessing your data before you can apply Kmean or most of the ML algorithms .  
 &#xA;1. Categorical dataset : i.e your data is in the form of multiple categories like column of fruits with values of Apple , orange ,banana etc. Then you can use "one hot encoding" method that will transform your category column into multiple columns that each

indicate if the sample is belong to the relevant category (i.e for column with 3 fruit types you will get 3 new binary (1 or 0) columns - is apple ? is orange? is banana ? read more about how to do it in R here : [One hot encoding in R][1]&#xD;&#xA;&#xD;&#xA;Update: like some suggested in the comments , K means wont be the best approach for clustering categorical data and in some cases you can get much better results when using more suitable approaches .Here is a link to another (more advanced) method for clustering categorical data in R - ROCK algorithem ([kaggle notebook][2]) . Also ,you can read about &quot;Kmode&quot; which is similar to kmeans for categories and [implemented in R][3]&#xD;&#xA;&#xD;&#xA;&#xD;&#xA;&#xD;&#xA; 2. If your dataset is plain text (like tweets or stackexchange posts) :&#xD;&#xA;One common method is using td-idf (but there are many more) , you can read more here:&#xD;&#xA;[ --> Word Count (39)

 question!&#xD;&#xA;&#xD;&#xA;## Some Remarks ##&#xD;&#xA;For imbalanced data you  
 have different approaches. Most well-established one is [resampling][1]  
 (Oversampling small classes /underssampling large classes). The other one is to  
 make your classification hierarchical i.e. classify large classes against all  
 others and then classify small classes in second step (classifiers are not  
 supposed to be the same. Try model selection strategies to find the  
 best).&#xD;&#xA;&#xD;&#xA;## Practical Answer ##&#xD;&#xA;&#xD;&#xA;I have got  
 acceptable results without resampling the data! So try it but later improve it  
 using resampling methods (statistically they are kind of A  
 MUST).&#xD;&#xA;&#xD;&#xA;TFIDF is good for such a problem. Classifiers should  
 be selected through model selection but my experience shows that Logistic  
 Regression and Random Forest work well on this specific problem (however it's  
 just a practical experience).&#xD;&#xA;&#xD;&#xA;You may follow the code bellow  
 as it worked simply well then you may try modifying it to improve your  
 results:&#xD;&#xA;&#xD;&#xA;&#xD;&#xA; train = pd.read\_csv(...)&#xD;&#xA;  
 test = pd.read\_csv(...) &#xD;&#xA; &#xD;&#xA; # TFIDF Bag Of Words
