

Problem04

September 26, 2019

```
[13]: #####  
#  
# Ulysses Carlos -- 09/25/2019  
# Problem 04  
#  
# Using the PostHistory file, provide a total count of the words used by each  
# distinct user. In other words, count all words in all posts for each user  
# and display this to screen. You can only identify users by the  
# UserID (30 points). You get 15 bonus points if you get the actual  
# DisplayName of the user.  
#  
#####  
  
sc.stop()  
from pyspark import SparkConf, SparkContext  
conf = SparkConf().setMaster("local").setAppName("My App")

 UserId="780" Comment="Added some intuition" Text="Spam filtering, especially in email, has been revolutionized by neural networks, here are a couple papers that provide good reading on the subject:

On Neural Networks And The Future Of Spam 
A. C. Cosoi, M. S. Vlad, V. Sgarciu 
http://ceai.srait.ro/index.php/ceai/article/viewFile/18/8

Intelligent Word-Based Spam Filter Detection Using 
Multi-Neural Networks 
Ann Nosseir, Khaled Nagati and Islam Taj-Eddin
http://www.ijcsi.org/papers/IJCSI-10-2-1-17-21.pdf

Spam Detection using Adaptive Neural Networks: Adaptive Resonance Theory 
David Ndumiyana, Richard Gotor, and Tarisai Mupamombe
http://onlineresearchjournals.org/JPESR/pdf/2013/apr/Ndumiyana%20et%20al.pdf

EDIT:
The basic intuition behind using a neural network to help with spam filtering is by providing a weight to terms based on how often they are associated with spam.

Neural networks can be trained most quickly in a supervised -- you explicitly provide the classification of the sentence in the training set -- environment. Without going into the nitty gritty the basic idea can be illustrated with these sentences:

Text = "How is the loss of the Viagra patent going to affect Pfizer";, Spam = false
Text = "Cheap Viagra Buy Now";, Spam = true

 UserId="819" Text="> But I don't know what is difference between text
 classification and topic models in documents

Text
 classification is a form of supervised learning -- the set of possible classes
 are known/defined in advance and don't change.

Topic modeling
 is a form of unsupervised learning (akin to clustering) -- the set of possible
 topics are unknown apriori. They're defined as part of generating the topic
 models. With a non-deterministic algorithm like LDA, you'll get different topics
 each time you run the algorithm.

 UserId="3223" Text="I would like to learn both Python and R for usage in data science projects. 

I am currently unemployed, fresh out of university, scouting around for jobs and thought it would be good if I get some Kaggle projects under my profile.

However, I have very little knowledge in either language. Have used Matlab and C/C++ in the past. But I haven't produced production quality code or developed an application or software

in either language. It has been dirty coding for academic usage all along.

I have used a little bit of Python, in a university project, but I dont know the fundamentals like what is a package , etc etc. ie havent read the intricacies of the language using a standard Python --> Word Count (64)

UserId="819" Text="In terms of open source NLG components, I'm most familiar with Mumble and FUF/SURGE. They've got both similarities and differences, so it's hard to say which is better...

 [Mumble] (<https://code.google.com/p/sparser/source/browse/#svn%2Ftrunk%2FMumble>):

 - written in Lisp
 - [EPL license] (<http://www.eclipse.org/legal/epl-v10.html>)
 - based on tree-adjointing grammar
 - focuses on linguistic message planning

 [FUF/SURGE] (<http://www.cs.bgu.ac.il/surge/index.html>):

 - written in Lisp
 - GPL license
 - based on functional unification grammar
 - focuses on syntactic realization

 Since it sounds like you're interested in abstractive summarization (which is much harder than traditional extractive summarization), I'd recommend the following academic papers:

 - [Text Generation for Abstractive Summarization] (<http://www.nist.gov/tac/publications/2010/participant.papers/Rali.proceedings.pdf>)
 - [Framework for Abstractive Summarization using Text-to- --> Word Count (34)

 UserId="7979" Text="My company provides managed services to a lot of its clients. Our customers typically uses following monitoring tools to monitor their servers/webapps:

 1. OpsView
 2. Nagios
 4. Pingdom
 5. Custom shell scripts

Whenever any issue is found, an alert mail comes to our Ops team so that they act upon rectifying the issue.

As we manage thousands of servers, our Ops teams' inbox is flooded with email alerts all the time. Even a single issue which has a cascading effect, can trigger 20-30 emails.

Now, what I want to do is to implement a system which will be able to extract important features out of an alert email - like server IP address, type of problem, severity of problem etc. and also classify the emails into proper category, like `CPU-Load-Customer1-Server2, MySQL-Replication-Customer2-DBServer3` etc. We will then have a pre-defined set of debugging steps for each category, in order to help the Ops team to rectify the problem faster. Also, the feature extractor will provide input data to the team for a problem.

So far I have been able to train *NaiveBayesClassifier* with supervised learning techniques i.e. labeled training data(cluster data), and able to classify new unseen emails into its proper cluster/category. As the emails are based on certain templates, the accuracy of the classifier is very high. But we also get alert emails from custom scripts, which may not follow the templates. So, instead of doing supervised learning, I want to try out unsupervised learning for the same. I am looking into *KMeans

clustering*. But again the problem is, we won't know the number of clusters beforehand. **So, which algorithm will be best for this use case?** Right now I am using Python's TextBlob library for classification. Also, for feature extraction out of an alert email, I am looking into NLTK (<http://www.nltk.org/book/ch07.html>) library. I tried it out, but it seems to work on proper English paragraphs/texts well, however, for alert emails, it extracted a lot of unnecessary features. **Is there already any existing solution for the same? If not, what will be the best way to implement the same? Which library, which algorithm? **PS: I am not a Data Scientist. **Sample emails:**

 UserId="8152" Text="First of all, I hope I'm in the right StackExchange here. If
 not, apologies!

I'm currently working with huge amounts of
 feature-value vectors. There are millions of these vectors (up to 20 million
 possibly). They contain some linguistic/syntactic features and their values are

all strings. Because most classifiers do not handle string data as values, I convert them to binary frequency values, so an attribute looks like this: @attribute 'feature#value' numeric And per row, the value is either 1 or it is absent (so note it's a *sparse* ARFF file). The thing is, with 250K rows, there are over 500K attributes and so, most algorithms have a hard time with this. There are a lot of algorithms. I'm really curious as to what you would consider a suitable one (preferably unsupervised, but anything works), and if you even have some ideas how I could improve performance. I can train on small subsets of data, but the results only get better when using large amounts of data (at least 7 million events).

For now, I've been using NaiveBayes variations (Multinomial and also DMNB --> Word Count (30))

 UserId="8465" Text="I have worked on building a fraud detection solution using text mining, so I understand the scenario that has led to this question. I'll talk about the approach/techniques that is to be followed to build the fraud detection solution. I'll divide it into 4 sections

- Build line of business fraud dictionary
- Fraud detection & scoring
- Tools
- Additional notes

###Building Fraud Dictionary:###

As a first step you'll have to identify fraud concepts with help from subject matter expert for the line of business in concern. Fraud concept is a person, characteristic, entity, or event that represents a suspicious scenario and similar concepts can be grouped together to form a concept category. Each concept is further represented by words, phrases, entities etc. The presence of these words/phrases in the document implies occurrence of fraud concept in that transaction. The end result of this exercise will be a fraud dictionary that is a repository of concepts and suspicious key words.

You can use NLP technique to build the dictionary. 

Steps:

 1) Convert the sentence to lowercase

 2) Remove stopwords, these are common words found in a language. Words like for, very, and, of, are, etc, are common stop words

 3) Extract n-gram i.e., a contiguous sequence of n items from a given sequence of text. simply increasing n, model can be used to store more context

 4) Assign a syntactic label (noun, verb etc.)

 5) Knowledge extraction from text through semantic/syntactic analysis approach i.e., try to retain words that hold higher weight in a sentence like Noun/Verb


###Fraud detection & scoring:###

Phrases/Keywords to be semantically matched with Phrases/Keywords from Fraud Dictionary and Fraud concepts in transactions can be identified. At this point, care needs to be taken to maintain the context (negation, positive sense) in which a keyword/phrase has been used to avoid false positives.

For each identified occurrence of Fraud concept in the transaction, a weight of 1 can be assigned. This is done for calculating a suspicious score for the transaction. Higher the score high suspicious.

Note that using a combination of larger data set with high textual content, and extensive fraud dictionary would result in higher number potentially identified.


###Tools:###

You can consider using OpenNLP / StanfordNLP for Part of Speech tagging. Most of the programming language have supporting library for OpenNLP/StanfordNLP. You can choose the language based on your comfort.


###Additional notes:###

- You can refer [here][1] to get an idea of extracting concepts from sentences

###Building Fraud Dictionary:###

As a first step you'll have to identify fraud concepts with help from subject matter expert for the line of business in concern. Fraud concept is a person, characteristic, entity, or event that represents a suspicious scenario and similar concepts can be grouped together to form a concept category. Each concept is further represented by words, phrases, entities etc. The presence of these words/phrases in the document implies occurrence of fraud concept in that transaction. The end result of this exercise will be a fraud dictionary that is a repository of concepts and suspicious key words.

For example considering the data set mentioned in the question, the `numeric patterns` become the concept category, and `fictitious invoice numbers` and `fictitiously-generated transaction amounts` are 2 different concepts. There will be a keywords/phrases that is associated to this concept which should be captured onto the fraud dictionary.

You can use NLP technique to build the dictionary. 

Steps:

 1) Convert the sentence to lowercase

 2) Remove stopwords, these are common words found in a language. Words like for, very, and, of, are, etc, are common stop words

 3) Extract n-gram i.e., a contiguous sequence of n items from a given sequence of text. simply increasing n, model can be used to store more context

If you open your `test.csv` in Notepad++ you will see something like this:

![file written from R][1]

If you edit it in Notepad++ so that it looks like 

![file edited in Notepad++] [2]

and then you run this:

testdf <- read.csv("test.csv";encoding="UTF-8")
testdf[1,3]
 testdf\$list2
plot(1:10,main=testdf[2,3])

You will see that there is no problem.

So in fact there are two problems:

 1. When writing Unicode text, R changes it back to system locale and then again to unicode, that's why writing data to csv file does not work correctly.

 2. R has problems showing Unicode data in `data.frame` so even after reading it correctly, `testdf` would print those codes there not the Unicode characters.

UserId="10337" Comment="added language code for syntax highlighting, fixed angular brackets" Text="My company provides managed services to a lot of its clients. Our customers typically uses following monitoring tools to monitor their servers/webapps:

 1. OpsView
 2. Nagios
 4. Pingdom
 5. Custom shell scripts

Whenever any issue is found, an alert mail comes to our Ops team so that they act upon rectifying the issue.

As we manage thousands of servers, our Ops teams' inbox is flooded with email

alerts all the time. Even a single issue which has a cascading effect, can trigger 20-30 emails. Now, what I want to do is to implement a system which will be able to extract important features out of an alert email - like server IP address, type of problem, severity of problem etc. and also classify the emails into proper category, like `CPU-Load-Customer1-Server2, MySQL-Replication-Customer2-DBServer3` etc. We will then have a pre-defined set of debugging steps for each category, in order to help the Ops team to rectify the problem faster. Also, the feature extractor will provide input data to the team for a problem. So far I have been able to train *NaiveBayesClassifier* with supervised learning techniques i.e. labeled training data(cluster data), and able to classify new unseen emails into its proper cluster/category. As the emails are based on certain templates, the accuracy of the classifier is very high. But we also get alert emails from custom scripts, which may not follow the templates. So, instead of doing supervised learning, I want to try out unsupervised learning for the same. I am looking into *KMeans clustering*. But again the problem is, we won't know the number of clusters beforehand. **So, which algorithm will be best for this use case?** Right now I am using Python's TextBlob library for classification. Also, for feature extraction out of an alert email, I am looking into NLTK (<http://www.nltk.org/book/ch07.html>) library. I tried it out, but it seems to work on proper English paragraphs/texts well, however, for alert emails, it extracted a lot of unnecessary features. **Is there already any existing solution for the same? If not, what will be the best way to implement the same? Which library, which algorithm?** **PS: I am not a Data Scientist.**

Sample emails:

Problem/Main objective/TLDR: Train a classifier, then feed it a random review and get the correspondent predicted review rating (number of stars from 1 to 5) - only 60% accuracy!
 :(

I have a big dataset with around 48000 tech product reviews (from many different writers and from different products - here this is not so important (?)) and corresponding ratings (1 to 5 stars) I randomly selected some reviews within each class:

 1 star: 173 reviews (could not pick 1000 because there were 173)
 2 stars: 1000 reviews
 3 stars: 1000 reviews
 4 stars: 1000 reviews
 5 stars: 1000 reviews

Total: 4173 reviews - this data is organized in one file (all_reviews_labeled.txt) in tuple format, one review and rating for line:

 ('review text', 'x star')
 ('review text', 'x star')
 ('review text', 'x star')
 ('review text', 'x star')

 ...

My 1st "dummie" aproach was:


 Tokenize review text
 POS tagging

 Get most frequent bigrams that folowing some POS tags rules for most frequent trigrams (I have seen this rules - using this POS patterns in "Automatic Star-rating Generation from --> Word Count (831)

 UserId="3151" Comment="added 583 characters in body" Text="I built a hierarchical clustering model and plotted a dendrogram for text data. There are instances where a word in its singular and plural form constitute a branch of the tree. This seems to be natural but this sort of duplicate complicates my clusters and making sense of data. How can I get rid of this phenomenon systematically? There might be a lot of these cases in my text data. I work in R.

Edit: I am using a solution proposed by Yanchang Zhao for the latest version of tm package but found this very slow. I am looking for an alternative way.

 myCorpusCopy <- myCorpus

 stemCompletion2 <- function(x, dictionary)

```

{&#xD;&#xA;    x &lt;- unlist(strsplit(as.character(x), &quot;
&quot;))&#xD;&#xA;    x &lt;- x[x != &quot;&quot;]&#xD;&#xA;    x &lt;-
stemCompletion(x, dictionary=dictionary)&#xD;&#xA;    x &lt;- paste(x,

 UserId="8820" Text="# Question 1: Category prediction

To
 predict the category of a new blog post, you could do the
 following:

* Build a MLP (multilayer Perceptron, a very
 simple neural network). Each category gets an output node, each tag is a binary
 input node. However, this will only work if the number of tags is very little.
 As soon as you add new tags, you will have to retrain the network.
*
 Build a MLP with "important words" as features.
* If you have
 internal links, you might want to have a look at "On Node Classification in
 Dynamic Content-based Networks". In case you're German, you might also like
 [Über die Klassifizierung von Knoten in dynamischen Netzwerken mit
 Inhalt](http://arxiv.org/abs/1512.04469)
* You could take all words you
 currently have, see those as a vector space. Fix that vocabulary (and probably
 remove some meaningless words like "with", "a",
 "an" - this is commonly called a "stopword"). For each text,
 you count the different words you have in your vocabulary. A new blog post is
 point in this space. Use \$k\$ nearest neighbor for classification.
* Use
 combinations of different predictions by letting each predictor give a vote for

a classification.

UserId="8820" Comment="added 86 characters in body" Text="# Question 1: Category prediction

To predict the category of a new blog post, you could do the following:

*
Build a MLP (multilayer Perceptron, a very simple neural network). Each category gets an output node, each tag is a binary input node. However, this will only work if the number of tags is very little. As soon as you add new tags, you will have to retrain the network.
*
Build a MLP with "important words"; as features.
*
If you have internal links, you might want to have a look at "On Node Classification in Dynamic Content-based Networks".. In case you're German, you might also like [Über die Klassifizierung von Knoten in dynamischen Netzwerken mit Inhalt] (http://arxiv.org/abs/1512.04469)
*
You could take all words you currently have, see those as a vector space. Fix that vocabulary (and probably remove some meaningless words like "with";, "a";, "an"; - this is commonly called a "stopword"). For each text, you count the different words you have in your vocabulary. A new blog post is point in this space. Use \$k\$ nearest neighbor for classification.
*
Use combinations of different predictions by letting each predictor give a vote for a classification.

[NLP][1] and and [text mining][2] are usually used for different goals.
Also, there is indeed an overlap and both definitions are vogue.

Other than the difference in goal, there is a difference in methods.
Text mining techniques are usually shallow and do not consider the text structure. Usually text mining will use bag of words, n-grams and possibly stemming over that.

In NLP methods usually involve the test structure. You can find there sentence splitting, part of speech tagging and parse tree construction.

 UserId="11097" Comment="deleted 4 characters in body" Text="I agree with Sean's
 answer.
[NLP][1] and [text mining][2] are usually used for different
 goals.
Also, there is indeed an overlap and both definitions are
 vogue.

Other than the difference in goal, there is a
 difference in methods.
Text mining techniques are usually shallow and
 do not consider the text structure.Usually, text mining will use bag of words,
 n-grams and possibly stemming over that.

In NLP methods
 usually involve the test structure. You can find there sentence splitting, part
 of speech tagging and parse tree construction. 

Typical
 text mining method will consider the following sentences to indicate happiness
 while typical NLP methods detects that they are not

 1. I am
 not happy
 2. I will be happy when it will rain
 3. If it will
 rain, I'll be happy.
 4. She asked whether I am happy
 5. Are

```

you happy?&#xD;&#xA;&#xD;&#xA; [1]:

UserId="381" Text="This seems like a matter of opinion to me, but here are some applications of machine learning that you seen _very_ often in Silicon Valley:

* **Advertising**
: what to show whom and when? The data comes fast and furious so the engineering part is quite sophisticated.
* **Recommendation**
: similar to the advertising problem, except there are no advertisers, and the volume is slower, so you can afford to use more sophisticated machine algorithms.
* **Security**
: did somebody outside penetrate your system? did somebody inside abuse your system?
* ** --> Word Count (70)

UserId="3570" Comment="formatted" --> Word Count (121)
UserId="17806" Text="It's not an easy question to answer even for groups with a
lot of leverage such as [Research Gate][1] (RG). RG has it's own (I assume
proprietary) `author matching algorithm` [which has caused problems in the
past][2].&#xD;&#xA;&#xD;&#xA;They use the name of the author (in different
combinations) to suggest [authorship to RG users][3] (so has you said, it does
causes a lot of problems). Every once in a while users that are not the author
accept the suggestions and, from the portal point of view, gain the equivalent
reputation. It's a serious business that requires quite a bit of R&D before
making a decision.&#xD;&#xA;&#xD;&#xA;That being said I can't answer with
certainties only with reasonable possibilities. A few questions I would make
(and hope to answer with a bit of data analysis):&#xD;&#xA;&#xD;&#xA;* What is
the probability that an author with a confirmed publication in an identified
journal will publish in that journal again? - **Journal
Name*&#xD;&#xA;&#xD;&#xA;* What is the probability that an author that has

```

partnered with other authors will repeat the same co-authoring combination?
****Co-author Names****

* What is the expected time story for publishing for each author? Authors rarely publish articles 20 years apart. Typically they publish more and more, or less and less. ****Time frame****

* How frequently do authors change the institution they belong to? ****Institution Name****

* What are the preferred keywords for a given author? ****Key Names****

* What are the preferred citations made by a given author?
****Bibliography****

All of the questions above require quite a bit of [Text Mining][4] and [String Matching][5], as well as solid dataset to start your mining.

Some publishers have their own [API][6] although I can't say much about permissiveness (never tried it myself). [RG has been promising one for years][7] but, as far as I know, it still does not [exist][8].

An unlikely thing I remember now is the inspiring story of [Aaron Swartz][9]. This activist, along with other persons, successfully managed to create large open archives for books and articles. Should that information still exist it might be worth your time to take a look [there][10].

Also if you have a list of the journals you are considering (you've mentioned only "doctors" which is a bit vague) you can try and see with the publisher if they have any way of accessing their database.

UserId="3024" Comment="I've found the solution. Here you are." Text="I have to filter a pandas data frame by matching a complex regular expression on a text index.&#xD;&#xA;&#xD;&#xA;The data frame is multi level indexed, and contains more than 2 million records.&#xD;&#xA;&#xD;&#xA;The way I'm doing is:&#xD;&#xA;&#xD;&#xA; identifiers = self._data.index.get_level_values('identifier')&#xD;&#xA; filt = ... # an_array_of_np.bool_with_the_same_length_as_my_data&#xD;&#xA;&#xD;&#xA; pattern = ... # a complex regular expression, as a string&#xD;&#xA; filt = filt & np.array(identifiers.str.contains(pat=pattern, case=False, regex=True), dtype=np.bool)&#xD;&#xA;&#xD;&#xA; ... # other filterings&#xD;&#xA;&#xD;&#xA;&#xD;&#xA;Unfortunately, the line beginning by `filt = filt &` is very slow.&#xD;&#xA;&#xD;&#xA;I'm wondering if you have some ideas to make it faster. I guess that's because of the `identifiers.str.contains`&#xD;&#xA;&#xD;&#xA;Thanks a lot!&#xD;&#xA;&#xD;&#xA;---&#xD;&#xA;&#xD;&#xA;EDIT:&#xD;&#xA;&#xD;&#xA;Thanks @Emre&#xD;&#xA;&#xD;&#xA;I'm not allowed to share those data, but the code below demonstrates the problem:&#xD;&#xA;&#xD;&#xA;- Step 0: 0:00:00.013527&#xD;&#xA;- Step 1: 0:00:00.010127&#xD;&#xA;- Step 2: 0:00:04.468114&#xD;&#xA;- Step 3: 0:00:02.109594&#xD;&#xA;- Step 4: 0:00:00.027437&#xD;&#xA;&#xD;&#xA;In fact, my feeling is that we apply the regular expression on all the values of the identifiers, while I would expect that the filter applies on the possible values of the index (lost of values are reused many times).&#xD;&#xA;&#xD;&#xA;import pandas as pd&#xD;&#xA; import numpy as np&#xD;&#xA; import datetime&#xD;&#xA; &#xD;&#xA; N = 2000000&#xD;&#xA; N_DVC = 10000&#xD;&#xA; &#xD;&#xA; def getData():&#xD;&#xA; identifiers = np.random.choice(np.array([&#xD;&#xA; &quot;need&quot;, &quot;need:

&#xD;
--&#xD;
        EDIT2&#xD;
        &#xD;
I've found a solution:
instead of filtering through all the values, I compute a hash table (in fact a
DataFrame) of the possible values and filter on those
values:&#xD;
        &#xD;
- Step 0: 0:00:00.014251&#xD;
- Step 1:
0:00:00.010097&#xD;
- Init fast filter: 0:00:00.353645&#xD;
- Step 2:
0:00:00.027462&#xD;
- Step 3: 0:00:00.002550&#xD;
- Step 4:
0:00:00.027452&#xD;
- Globally:
0:00:00.435839&#xD;
        &#xD;
        &#xD;
It runs faster because there are
lots of duplicated values.&#xD;
        &#xD;
Here's a class which is doing that
stuff. It works for indexes and normal columns:&#xD;
        class

```

```

DataFrameFastFilterText(object):&#xD;&#xA;          &quot;&quot;&quot;This class
allows fast filtering of text column or index of a data frame&#xD;&#xA;
Instead of filtering directly the values, it computes a hash of the
values&#xD;&#xA;          and applies the filtering to it.&#xD;&#xA;          Then,
it filters the values based on the hash mapping.&#xD;&#xA;          This is faster
than direct filtering if there are lots of duplicates values.&#xD;&#xA;
&quot;&quot;&quot;&#xD;&#xA;          &#xD;&#xA;          def __init__(self, data,
column):&#xD;&#xA;          &quot;&quot;&quot;Constructor&#xD;&#xA;
- data: pandas Data Frame&#xD;&#xA;          - column: name of the column -
the column can be an index&#xD;&#xA;          &quot;&quot;&quot;&#xD;&#xA;
self._data = data.copy() # working with a copy because we will make some
changes&#xD;&#xA;          self._column = column&#xD;&#xA;
self._hashedValues = None&#xD;&#xA;          self._initHashAndData()&#xD;&#xA;
&#xD;&#xA;          def _initHashAndData(self):&#xD;&#xA;
&quot;&quot;&quot;Initialize the hash and transforms the data&#xD;&#xA;
- data: Resets the index, rename the column as 'value' and drops all&#xD;&#xA;
the other columns&#xD;&#xA;          - hash: data frame of 'hashId',
'hashValue'&#xD;&#xA;          &quot;&quot;&quot;&#xD;&#xA;
self._data.reset_index(inplace=True)&#xD;&#xA;          self._data =
self._data.loc[:, [self._column]]&#xD;&#xA;
self._data.rename(columns={self._column: 'value'}, inplace=True)&#xD;&#xA;
self._hash = pd.DataFrame({'value':
pd.Series(self._data['value'].unique())})&#xD;&#xA;
self._hash['hashId'] = self._hash.index&#xD;&#xA;          self._data =
pd.merge(&#xD;&#xA;          left=self._data,&#xD;&#xA;
right=self._hash,&#xD;&#xA;          on='value',&#xD;&#xA;
how='inner',&#xD;&#xA;          )&#xD;&#xA;          &#xD;&#xA;          def
getFilter(self, *args, **kwargs):&#xD;&#xA;          &quot;&quot;&quot;Returns
the filter as a boolean array. It doesn't applies it.&#xD;&#xA;          -
args: positional arguments to pass to pd.Series.str.contains&#xD;&#xA;
- kwargs: named arguments to pass to pd.Series.str.contains&#xD;&#xA;
&quot;&quot;&quot;&#xD;&#xA;          h = self._hash.copy()&#xD;&#xA;
h = h.loc[h['value'].str.contains(*args, **kwargs), :].copy()&#xD;&#xA;
filt = np.array(&#xD;&#xA;
self._data['hashId'].isin(h['hashId'])),&#xD;&#xA;
dtype=np.bool&#xD;&#xA;          )&#xD;&#xA;          return
filt.copy()&#xD;&#xA;&#xD;&#xA;And the example code is adapted as
follows:&#xD;&#xA;&#xD;&#xA;          ...&#xD;&#xA;          tic =
datetime.datetime.now()&#xD;&#xA;          fastFilter = DataFrameFastFilter --> Word

UserId="20585" Text="I'm working with datumbox ml framework for sentiment analysis.[Here the git link][1]. I found a sentiment Ml code in code examples of frame work [here is the code example link][2]. I want to use same code for twitter-sentiment But in the code example,only two training datasets are used pos,neg But for Twitter sentiment analysis,I want to include Neutral sentiment also.I do have my own training datasets of pos & neg tweets but I don't any Neutral datasets.

My doubt is : 

1) Do I need to feed neutral training dataset for giving the neutral sentiment? 
or 

2) Do I need to predict neutral sentiment based on positive & negative training sets.if I need go for predicting then I need an idea on how to do that?

UserId="381" Text="They've created a graph from the news articles, topics, and named entities (locations, persons, companies, organizations). There are a lot of things going on here, but k-means is not one of them. If I had to do this I would use a named entity recognition (NER) and document embeddings (doc2vec, etc.). Once you have the embeddings, and the edges (thanks to NER), use a graph layout algorithm like force direction. If the graph is too dense, thin out the weaker edges. If all that sounds Chinese to you, start by reading about "named entity recognition", and "word embeddings". The idea is to attach a number (or rather, a vector) to everything from a word to a document.

Twitter is a different beast. The textual content, such as it is, won't play nice with these embedding algorithms, but you have hashtags and strong social signals; mentions, retweets, and follows. This is pretty complicated, too, so I'll leave you with a relevant paper: [Twitter-Network Topic Model: A Full Bayesian Treatment for Social Network and --> Word Count (2)

 UserId="15533" Comment="added 293 characters in body" Text="On the surface, this sounds like a pretty stupid question. But I've spend the day poking around various sources, and I can't find an answer. 

Let me make the question more clear. 

Take this classic image. 

[![enter image description here][1]][1]

Clearly the input layer is a vector with 3 components. Each of the three components is propagated to the hidden layer. Each neuron in the hidden layer is seeing the same vector with 3 components -- all neurons see the same data. 

So we are at the hidden layer now. From what I read, this layer is all just (usually) ReLus or sigmoids. 

Correct me if I'm wrong, but a ReLu is a ReLu. Why would you need 4 of the exact same function, all seeing the exact same data? 

What makes the red neurons in the hidden layer different from each other? Are they supposed to be different? I haven't read anything about tuning or setting parameters or perturbing different neurons to have them be different. But if they aren't different...then what's the point?

 UserId="14" Comment="Added full citation in the link to the paper. (This will make it easier to find if the link becomes broken.)" Text="The IDF part of TF-IDF gives less weight to a word if it occurs in a large fraction of the documents in your corpus. However, this doesn't necessarily mean that the word is unimportant for distinguishing your two classes. A word which is common in your corpus, but which also occurs substantially more often in one class than the other, could very well be quite valuable in distinguishing the classes. This can especially be true if your set is not balanced between the two classes.

For example:

Suppose that 95% of negative reviews contained the term "boring", while only 5% of the positive reviews contained "boring". If this occurred in a balanced set of negative and positive reviews, that means that half the total reviews would contain "boring", and this might be one of the terms whose weight is more strongly suppressed by IDF, despite the fact that it's obviously a valuable term for distinguishing the classes. If instead 90% of the reviews are negative (with "boring" again occurring in 95% of negative reviews and 5% of positive ones), then a full 86% of your documents contained the term, and its weight might be highly suppressed by IDF despite its obvious importance.

In essence, the problem is that TF-IDF is agnostic to the class labels in your training set. One alternative to TF-IDF for text classification that doesn't have this flaw is Bi-Normal Separation (BNS), see for example this paper:

UserId="25742" Comment=" Inserted code here, from my github" Text="Am currently working on something in this domain.

The rough process I am currently following is -

 1. Extract data from PDFs (ubiquitous version of Bank Statements nowadays) into more usable formats. Currently,converting them to TXT files first as an intermediate step.
 2. Generically, bank statements (from a specific bank) tend to be structured in the same format. Hence, while converting the TXT to CSV, you can structure the algo such that it knows what to pick up - based on a rough analysis of the TXT file.
- Use 2 different data frames to store the statements content - one df keeping track of the transactional data (storing 3 values - Date, Description and Amount) and the other to keep track of the metadata (storing 2 values - Key and Value)
- You can determine the rough structure of the TXT file by going through a few TXTs. e.g. the transactions generally begin after a specific element's occurrence in every bank statement. Ignore the page footers / headers that recur in case of multi-page transactions. Also, another observation would be that all data in a specific column of the transactions (the transactions are read in as a table by my program [link given below]) appear together. 
- Doing the above enables the transaction and meta data to a relatively structured and processable format 

 3. Perform analysis on the Description column or the entire transactional df you have thus generated.

You can use the following code to convert a given PDF to a txt file -

 from __future__ import unicode_literals
 import os
 import sys 
 reload(sys) 
 sys.setdefaultencoding('utf8')
 from pdfminer.pdfinterp import PDFResourceManager, PDFPageInterpreter
 from pdfminer.pdfpage import PDFPage
 from pdfminer.converter import XMLConverter, HTMLConverter, TextConverter
 from pdfminer.layout import LAParams
 from cStringIO import StringIO
 
 def pdfparser(data):
 dest = data[:-3]+'"txt" 
 print "\n\n\n\n";dest 
 fp = file(data, 'rb')
 rsrcmgr = PDFResourceManager()
 retstr = StringIO()
 codec = 'utf-8'
 laparams = LAParams()
 device = -->

 UserId="12558" Text="If I understand correctly you want to cluster urls by using the keywords extracted as features. As these features are really sparse, you can

try to use dimensionality reductions methods to help you.

One way is to treat each URL keywords as a document. Then you can use document embeddings algorithms such as [LDA][1] or [doc2vec][2] that learn denser representations of your documents.

If you want to group keywords, you can try to use word embeddings methods that learn representations of words. Using this you can then measure the similarity between words and groups of words.
An example is the well-known [word2vec][3]. Recent methods like [FastText][4] can be alternative that take the morphology into account.

 UserId="7952" Text="I am staying quite generic since you asked for enlightenment, just mentioning some possible directions that you can explore.

You have basically two possibilities:

 1. Classification of the text (Supervised learning).

Supervised means
 that you need first to externally apply labels (for example manually by humans) to examples of texts
 (labels could be "politics" or "show";) and then use one of the
 classification algorithms.
 You have extracted words from the text,
 so you could use a "bag of words" approach for classifying.
 There exist adaptations
 of classification algorithms (multi-label classification) in order to
 provide multiple labels (such as one text is labelled both with
 "music" and "movie").

 You can find text corpora already pre-labelled, to train the algorithm and partly avoid the manual effort. 

 2. Clustering the text, topic modelling (unsupervised learning).

In this case you do not need to provide examples with labels but the algorithm will cluster the texts according to parameters like the similarity of two texts or on keywords/topics extracted from the texts.

Although this method do not require labeled examples, the clusters you get as output will require fine tuning, e.g. number of clusters to produce, names of the clusters, etc.

Since you mentioned SKlearn, you can find some directions on their web site: [Text Feature Extraction][1].

 To maintain, control and enhance the quality of document images and minimize the negative impact of degradations on various analysis and processing systems, it is critical to understand the types and sources of degradations and develop reliable methods for estimating the levels of degradations. This paper provides a brief survey of research on the topic of document image quality assessment. We first present a detailed analysis of the types and sources of document degradations. We then review techniques for document image degradation modeling. Finally, we discuss objective measures and subjective experiments that are used to characterize document image quality. [\[Subjective and Objective Quality Assessment of Image: A Survey\]](https://www.researchgate.net/profile/Vipin_Kamble3/publication/2762715) (https://www.researchgate.net/profile/Vipin_Kamble3/publication/2762715)
 With the increasing demand for image-based applications, the efficient and reliable evaluation of image quality has increased in importance. Measuring the image quality is of fundamental importance for numerous image processing applications, where the goal of image quality assessment (IQA) methods is to automatically evaluate the quality of images in agreement with human quality judgments. Numerous IQA methods have been proposed over the past years to fulfill this goal. In this paper, a survey of the quality assessment methods for conventional image signals, as well as the newly emerged ones, which includes the high dynamic range (HDR) and 3-D images, is presented. A comprehensive explanation of the subjective and objective IQA and their classification is provided. Six widely used subjective quality datasets, and performance measures are reviewed. Emphasis is given to the full-reference image quality assessment (FR-IQA) methods, and 9 often-used quality measures (including mean squared error (MSE), structural similarity index (SSIM), multi-scale structural similarity index (MS-SSIM), visual information fidelity (VIF), most apparent distortion (MAD), feature similarity measure (FSIM), feature similarity measure for color images (FSIMC), dynamic range independent measure (DRIM), and tone-mapped images quality index (TMQI)) are carefully described, and their performance and computation time on four subjective quality datasets are evaluated. Furthermore, a brief introduction to 3-D IQA is provided and the issues related to this area of research are reviewed. [\[No-reference image quality assessment algorithms: A survey\]](https://www.researchgate.net/profile/Vipin_Kamble3/publication/2762715) (https://www.researchgate.net/profile/Vipin_Kamble3/publication/2762715)

41_No-reference_image_quality_assessment_algorithms_A_survey/links/5726d3d208ae262228b21594.pdf)
> valuation of noise content or distortions present in an image is same as assessing the quality of an image. Measurement of such quality index is challenging in the absence of reference image. In this paper, a survey of existing algorithms for no-reference image quality assessment is presented. This survey includes type of noise and distortions covered, techniques and parameters used by these algorithms, databases on which the algorithms are validated and benchmarking of their performance with each other and also with human visual system.

[Objective image quality assessment: a survey](<http://www.tandfonline.com/doi/abs/10.1080/00207160.2013.816415>)
> Image quality assessment (IQA) is critically important for the image-processing field. IQA aims to build a computational model to predict human perceived image quality, accurately and automatically. Until now, great efforts have been employed to design IQA metrics. In this paper, we systematically and comprehensively review the fundamental, brief history, and state-of-the-art developments of IQA, with emphasis on natural image quality assessment (NIQA). First, the definition of image quality is discussed, which contains three aspects and lead to different philosophies of designing IQA metrics. Afterwards, classic NIQA metrics are presented with some further discussions. Widely used databases and the performances of classic NIQA metrics on them are also listed. We highlight the most significant works and some open issues about the developments of IQA, and provide the benchmarks for the researchers and scholars who work on

IQA.

[Document Image Quality Assessment Using Discriminative Sparse Representation](https://www.researchgate.net/profile/Xujun_Peng/publication/286929531_Document_Image_Quality_Assessment_Using_Discriminative_Sparse_Representation/links/5714643d08aeebe07c064296.pdf)
> The goal of document image quality assessment (DIQA) is to build a computational model which can predict the degree of degradation for document images. Based on the estimated quality scores, the immediate feedback can be provided by document processing and analysis systems, which helps to maintain, organize, recognize and retrieve the information from document images. Recently, the bag-of-visual-words (BoV) based approaches have gained increasing attention from researchers to fulfill the task of quality assessment, but how to use BoV to represent images more accurately is still a challenging problem. In this paper, we propose to utilize a sparse representation based method to estimate document image's quality with respect to the OCR capability. Unlike the conventional sparse representation approaches, we introduce the target quality scores into the training phase of sparse representation. The proposed method improves the discriminability of the system and ensures the obtained codebook is more suitable for our assessment task. The experimental results on a public dataset show that the proposed method outperforms other hand-crafted and BoV based DIQA approaches.

[Discrete Orthogonal Moments Based Framework for Assessing Blurriness of Camera Captured Document Images](http://link.springer.com/chapter/10.1007/978-3-319-30348-2_18)
> One of the most widely used tasks in the area of image processing is automated processing of documents, which is done using Optical Character Readers (OCR) from document images. The

most common form of distortion in document images is blur which can be caused by defocus, motion, camera shake etc. In this paper we propose a no reference image sharpness measure framework using discrete orthogonal moments and image gradients for assessing quality of document images and validated the results against state of the art image sharpness measures and accuracy of three well known Optical Character Readers.

UserId="18429" Text="**Short Version:** How do I get renderUI to react to a
drop-down list that is in a wellPanel that contains a submitButton *without
having to click the submitButton*?&#xD;&#xA;&#xD;&#xA;**Long Version:** I am
building a Shiny app to perform many different analyses on a large dataset. The
user will select their analysis from a drop-down list at the top of a wellPanel.
Depending on the analysis selected, I'd like to provide a different set of
additional inputs/filters in the wellPanel with a submitButton at the
bottom.&#xD;&#xA;&#xD;&#xA;I would like the user to have to change the dynamic
inputs, then click the submitButton for their inputs to take effect. However, I
want the renderUI function to react to the drop-down list at the top *without*
the submitButton being clicked. From what I've read, I think I need to use
observeEvent or something similar, but I can't figure it
out.&#xD;&#xA;&#xD;&#xA;Here is a simplified version of what I'm building.
Changing the drop-down list selection and clicking submit will change the
inputs. Submit will also change the text rendered on the right. However, I need
to uncouple the dynamic UI from the submit button. Any help is much
appreciated.&#xD;&#xA;&#xD;&#xA;ui.r:&#xD;&#xA;&#xD;&#xA;library(shiny)
&#xD;&#xA;&#xD;&#xA;ui <- fluidPage(&#xD;&#xA;fluidRow(&#xD;&#xA;
column(4,wellPanel(&#xD;&#xA;selectInput(&quot;analysis&quot;,
label = &quot;Type of Analysis:&quot;, &#xD;&#xA;
c(&quot;Award Total&quot; = &quot;total&quot;, &#xD;&#xA;
&quot;Award Average&quot; = &quot;average&quot;),&#xD;&#xA;
width = validateCssUnit(&quot;70%&quot;)),&#xD;&#xA;
uiOutput(&quot;filter_box&quot;)),&#xD;&#xA;
submitButton(&#xD;&#xA;)),&#xD;&#xA;column(8,
textOutput(&quot;sample_text&quot;))&#xD;&#xA;)&#xD;&#xA;
)&#xD;&#xA;&#xD;&#xA;server.r:&#xD;&#xA;&#xD;&#xA;shinyServer(function(input, output) {&#xD;&#xA;
output$filter_box <- renderUI({&#xD;&#xA;if(input$analysis ==
&quot;total&quot;){&#xD;&#xA;tagList(radioButtons(inputId =
&quot;input1&quot;, label = &quot;Select One:&quot;,c(&quot;A&quot;,
&quot;B&quot;, &quot;C&quot;), selected = &quot;A&quot;))&#xD;&#xA;} else
{&#xD;&#xA;tagList(checkboxGroupInput(inputId = &quot;input2&quot;, label
= &quot;Select all that apply:&quot;,c(&quot;1&quot;,&quot;2&quot;,&quot;3&quot;,
&quot;4&quot;,&quot;5&quot;)),&#xD;&#xA;dateRangeInput(inputId =

flow (like a template) to be followed while on text analysis projects. So far, I've come up with this.

Text Analytics Steps

1. Data Collection
 - a. Acquire data
 - b. Convert data into plain text
2. Remove Duplicate Entries
3. Text Parsing and Extracting Features
 - a. Tokenization
 - b. Parsing
 - i. Remove HTML characters
 - ii. Decode complex symbols to UTF-8
 - iii. Spell check
 - iv. Apostrophe look-up
 - v. Remove punctuation marks
 - vi. Remove expressions / emojis
 - vii. Split attached words
 - viii. Slangs look-up
 - ix. Remove URLs
 - c. Lemmatization / Stemming (Normalization of Tokens)
 - d. Parts-of-Speech Tagging
4. Text Filtering
 - a. Remove start-words
 - b. Remove stop-words
 - c. Remove irrelevant words based on frequency
5. Text Transformation
 - a. Bag of Words Representation
 - b. TF-IDF
6. Text Mining / Analysis (whichever analysis needed)
 - a. Text Categorization
 - b. Text Classification (supervised)
 - c. Topic Modeling (unsupervised)
 - d. --> Word Count (47)

 UserId="30043" Text="Text mining is rather a tricky field of machine learning application, since all you've got is 'unstructured and semi structured data' and the preprocessing and feature extraction step matters a lot. [The text mining handbook][1] is a priceless reference in this area of research. but to be specific about your case, I can suggest two answers:

- as noted, preprocessing step plays a very important role here. in text mining it is likely to get trapped inside the curse of dimensionality, since you probably have say around 1000 documents but more than 15000 unique words in a dataset. techniques such as stemming and lemmatizing, static and dynamic stopword and punctuation erasing all aim solving this issue. So preprocessing and feature extraction is not an option. it is a MUST

- Naive Bayes model is a linear classifier. Even though it is a very popular algorithm in text classification, there are still risks of rising such problems as yours. the main reason could be that your word-space matrix is highly sparse. you must have paid

attention to the fact that in calculating the posterior probability of belonging to a class, Naive Bayes, naively multiplies all single probabilities of $P(y|x_i)$. and if there is at least one zero probability, your final answer would be zero, no matter what other inverse observation probabilities are. If you have implemented the algorithm yourself, try already-constructed tools in MATLAB, Python sci-kit learn library, or data mining softwares like KNIME and RapidMiner. they have delicately handled such practical issues in implementing Naive Bayes algorithm.

 https://datascience.stackexchange.com/" Text="I have worked on building a fraud
 detection solution using text mining, so I understand the scenario that has led
 to this question. I'll talk about the approach/techniques that is to be followed
 to build the fraud detection solution.I'll divide it into 4
 sections

;- Build line of business
 fraud dictionary
;- Fraud detection & scoring
;-
 Tools
;- Additional
 notes

###Building Fraud
 Dictionary:###

As a first step you'll have to identify fraud
 concepts with help from subject matter expert for the line of business in
 concern. Fraud concept is a person, characteristic, entity, or event that

represents a suspicious scenario and similar concepts can be grouped together to form a concept category. Each concept is further represented by words, phrases, entities etc. The presence of these words/phrases in the document implies occurrence of fraud concept in that transaction. The end result of this exercise will be a fraud dictionary that is a repository of concepts and suspicious key words.

For example considering the data set mentioned in the question, the `numeric patterns` become the concept category, and `fictitious invoice numbers` and `fictitiously-generated transaction amounts` are 2 different concepts. There will be a keywords/phrases that is associated to this concept which should be captured onto the fraud dictionary.

You can use NLP technique to build the dictionary.

Steps:

- 1) Convert the sentence to lowercase
- 2) Remove stopwords, these are common words found in a language. Words like for, very, and, of, are, etc, are common stop words
- 3) Extract n-gram i.e., a contiguous sequence of n items from a given sequence of text. simply increasing n, model can be used to store more context
- 4) Assign a syntactic label (noun, verb etc.)
- 5) Knowledge extraction from text through semantic/syntactic analysis approach i.e., try to retain words that hold higher weight in a sentence like Noun/Verb

###Fraud detection & scoring:###

Phrases/Keywords to be semantically matched with Phrases/Keywords from Fraud Dictionary and Fraud concepts in transactions can be identified. At this point, care needs to be taken to maintain the context (negation, positive sense) in which a keyword/phrase has been used to avoid false positives.

For each identified occurrence of Fraud concept in the transaction, a weight of 1 can be assigned. This is done for calculating a suspicious score for the transaction. Higher the score high suspicious.

Note that using a combination of larger data set with high textual content, and extensive fraud dictionary would result in higher number potentially identified.

###Tools:###

You can consider using OpenNLP / StanfordNLP for Part of Speech tagging. Most of the programming language have supporting library for OpenNLP/StanfordNLP. You can choose the language based on your comfort.

###Additional notes:###

- You can refer [here][1] to get an idea of extracting concepts from sentences

I tried using naiveBayes() from e1071 library but it seems that while training, it doesn't accept multi-label class variable.

I created TermDocumentMatrix using the text

document corpus and tried to create the model using this matrix and class variable(list of topics a particular document belongs to). Below is the code that I used.

```

trainvector <- as.vector(traindata$body -->

[Text Summarization within the LSA
 Framework] [1]

 ;
In section 2.1, the author discusses document summarization
 approaches based on sentence extraction. He identifies five
 approaches:

- Surface Level Approaches
- Corpus-
 based Approaches
- Cohesion-based Approaches
- Rhetoric-based
 Approaches
- Graph-based Approaches

(The "First
 Sentence Approach" belongs to the *Surface Level Approaches".) The
 author further describes these approaches and compares
 them.

Khodra,

 UserId="-1" Comment="replaced http://stackoverflow.com/ with
 https://stackoverflow.com/" Text="First of all I should mention that this is an
 OS specific question. You will see this problem in Windows but not in Linux (I'm
 not sure about OS X, but maybe no problem there too.)

The
 problem with your code is not with the reading part.
If you open your
 `test.csv` in Notepad++ you will see something like
 this:

![file written from R][1]

If you
 edit it in Notepad++ so that it looks like 

![file edited in
 Notepad++][2]

and then you run this:


 testdf <- read.csv("test.csv",encoding="UTF-8")

 testdf[1,3]
 testdf\$list2

 plot(1:10,main=testdf[2,3])

You will see that there is no
 problem.

So in fact there are two
 problems:

 1. When writing Unicode text, R changes it back to
 system locale and then again to unicode, that's why writing data to csv file
 does not work correctly.

 2. R has problems showing Unicode
 data in `data.frame` so even after reading it correctly, `testdf` would print
 those codes there not the Unicode characters.

see this
 question on [Writing Unicode Text into Text File from R (in Windows)][3] in R
 mailing list archives,
and also this question on [UTF-8 file output in

R] [4] on stackoverflow.

 UserId="35481" Text="Referencing @JahKnows answer, I think what he may be trying to refer to is **stemming** not **n-grams**. (I would've commented but not enough reputation). Using the python package nltk it should allow you to stem the words given that you want to only get the roots of each word.

From what I've worked on, **n-grams** are sequences of words with length **n**. They are still very helpful for the **bag of words** suggestion. The python library scikit-learn has a class **CountVectorizer**

which lets you create this model. In addition, it also lets you set a **max** number of features which can act as your feature reduction.

Further, if you were going this route, I would continue and use **Tf-idf** which will find out 'how important' a word is to a document. You can read more on the [wiki][1]. Scikit-learn has a great tutorial on working with text data which utilizes both **CountVectorizer** and **Tf-idf**:

 UserId="35902" Text="Thanks for the real-world problem! Interesting challenge

there. Some thoughts:

- regex (regular expressions) may not work because "*Whole Cheese*" (the description) doesn't even contain "*pizza*" (the category)!
- the "case-when logic" you mentioned is SQL's equivalent of handling conditional (if/else) logic using SQL's `CASE` statement. This can be helpful but super-tedious due to the huge number of rules required. (And then what happens when you have misspelt descriptions e.g. *pizzza*?)
- wrt the comment by @Spaceman, my thought is that using `stringdist` to calculate string distance to then perform clustering, which is unsupervised, wastes all the useful labelled data which can be used!

My suggestion:

Use a combination of "case-when logic" and classification algorithms, to generate a set of labelled data (the labels being the rollups) in which then you can perform some supervised classification for the unlabelled data.

In your sample file, some categories have already been labelled. You can use that as training data for your supervised learning (e.g. SVM).

This may require some text mining knowledge (e.g. `DocumentTermMatrix`, tokenizers). I refer you to the wonderful `tm` and `R --> Word Count (4)

 UserId="37280" Text="I'm a neuroscientist, and I encountered what I think is a similar issue. Just to give a little background: the brain is divided in ~ 200k voxels. Using a technique known as DTI, fibers are sought. Either a fiber passes through a certain voxels (1), or it doesn't (0). Therefore, given a certain voxel, the connections pattern with the rest of the brain is a 200k vector; its components being mostly 0s, sometimes 1.

a) either calculate the cross-correlation matrix between all vectors of your dataset, or the distance matrix; in both cases, you'll get a square matrix.
Which distance to choose: I would suggest the Jaccard distance, eminently suitable for binary, sparse feature vectors.

b1) use the spectral reordering algorithm, as described in <http://www.pnas.org/content/suppl/2004/08/20/0403743101.DC1/03743Supp> --> Word Count (59)

 UserId="16024" Text="I'm working on [Seq2Seq model] using LSTM from Keras (using Theano background) and I would like to parallelize the processes, because even few MBs of data need several hours for training. 

It is clear that GPUs are far much better in parallelization than CPUs. At the moment, I only have CPUs to work with. I could access 16 CPUs(2 Threads per core X 4 cores per socket X 2 sockets)

From the doc of multi-core [support] in Theano, I managed to use all the four cores of a single socket. So, basically the CPU is at 400% usage with 4CPUs used and the remaining 12 CPUs remain unused. How do I make use of them too. Tensorflow could also be used instead of Theano background, if it works.

 UserId="8041" Text="Facebook's [fasttex][1] is really great for loosely formatted text. Fasttext is a library for doing several tasks, the one you'll want to use is text classification. The best part of fasttext it uses character n-grams that instead of working with full words (which @JahKnows described well). The hardest part of using the tool is formatting the training data properly, but just look through the provided example and you should get it pretty quickly.

 UserId="16024" Comment="updates about new models." Text="Word2vec works in two models CBOW and skip-gram. Let's take CBOW model, as your question goes in the same way that predict the target word, given the surrounding

words. Fundamentally, the model develops input and output weight matrices, which depends upon the input context words and output target word with the help of a hidden layer. Thus back-propagation is used to update the weights when the error difference between predicted output vector and the current output matrix. Basically speaking, predicting the target word from given context words is used as an equation to obtain the optimal weight matrix for the given data. To answer the second part, it seems a bit complex than just a linear sum.

1. Obtain all the word vectors of context words
2. Average them to find out the hidden layer vector h of size $N \times 1$
3. Obtain the output matrix $syn1$ (`word2vec.c` or `gensim`) which is of size $V \times N$
4. Multiply $syn1$ by h , the resulting vector will be z with size $V \times 1$
5. Compute the probability vector $y = \text{softmax}(z)$ with size $V \times 1$, where the highest probability denotes the one-hot representation of the target word in vocabulary.

V denotes size of vocabulary and N denotes size of embedding vector.

Update: Long short term memory models are currently doing a great work in predicting the next words. [seq2seq] models are explained in [tensorflow tutorial]. There is also a [blog post] about text generation. [seq2seq]:

UserId="38419" Text="For text classification in your case, it can be solved by training a binary classes classification network.
Main steps as follows:

*
1. Training data preparation*

Two classes data are needed, one class contain job ad text, and the other does not contain job ad.

*
2. Building the network*

Building a binary classification network with Keras, Caffe or any other DL library you like.

*
3. Train the network*

Training the network on the data prepared above.

*
4. --> Word Count (24)

 1. given a sound, we want to know if it's of class A
 2. given a sound, we want to know if it's of class B

This way of putting it is valuable to some techniques, notably "one-class classification" and "PU learning" (learning from positive and unlabeled examples). These techniques are very relevant when you want to know "does my item follow a given distribution D?", which is exactly what you're looking for.

Still, if you have (or can collect) a lot of data that is neither A nor B, you may simply label it as a garbage class C and use a common classifier - however, it may actually be harmful, because you're likely assuming wrong things about class C [Li, Liu and Ng, "Negative Training Data can be Harmful to --> Word Count (20)

 UserId="41514" Text="**PROBLEM:**

Suppose if I have a small dataset containing some words and their tags/labels.
The main task is to provide tags to other words(which are not in the dataset) based on their contextual relationship with the words already in the dataset.

Let's say, for example, my custom dataset includes

Soap --> label__(cleaning_agent)
pencil--> label__(stationary_item)
mobile--> label__(electronics)
washingmachine--> label(electronics)
and so on.


I want my program to be able to correctly predict the label of an unknown word, e.g.

washing powder to its correct category
label__(cleaning_agent)
radio to label__(electronics) etc.

ACTIONS:

Now the main problem is to find the relation between two words based on context, but I am not able to decide what can be the parameters for finding that.

I have tried a naive approach using datamuse API and fastText library.

Naive approach is as follows->
step 1-> find all the related words of the given word(let's say W) e.g. pencil using datamuse API.
step 2-> combine them into a string(let's say S) with spaces in between them
step 3-> use the label name, W, S as the training dataset for fastText.

NOTE: fastText requires label name, word, sentence(can be from news articles, blogs, Wikipedia etc) as a context for that word.

RESULTS:
fast --> Word Count (79)

 UserId="42657" Text="Twitter has rules that limit sharing of complete datasets, instead limiting sharing to the tweet ids (see this [discussion][1] and the [developer agreement][2]). Tools such as [twarc][3] can be used to "rehydrate" the tweet metadata by calling the Twitter api and retrieving the info. The Twitter API has rate limiting which can make this a somewhat slow process.

For a package that works in R, see [RTextTools][4] or check out [RWeka][5] which bridges the gap between R and Java to use Weka. If using Python, you can also use scikit-learn's svm implementation.

 UserId="29575" Comment="Provide some text" Text="Natural language processing (NLP) is a subfield of artificial intelligence that involves transforming or extracting useful information from natural language data. Methods include machine-learning and rule-based approaches. It is often regarded as the engineering arm of Computational Linguistics.

 NLP tasks

 * Text pre-processing
 * Coreference resolution
 * Dependency parsing
 * Document summarization
 * Named entity recognition (NER) [tag:named-entity-recognition]
 * Information extraction (IE) [tag:information-retrieval]
 * Language modeling
 * Part-of-speech (POS) tagging
 * Morphological analysis and wordform generation
 * Phrase-structure (constituency) parsing 
 * Machine translation (MT) [tag:machine-translation]
 * Question answering (QA)
 * Sentiment analysis [tag:sentiment-analysis]
 * Semantic parsing 
 * Text categorization 
 * --> Word Count (42)

 UserId="43914" Text="I am trying to classify customer support sessions using supervised machine learning.

In each customer support session I have 3 bags of information.
1. The title of the customer's complaint 
2. Information about the device the customer was using
3.
